Efficient Industrial Robot Calibration via a Novel Unscented Kalman Filter-Incorporated Variable Step-Size Levenberg–Marquardt Algorithm

Zhibin Li[®], Shuai Li[®], Senior Member, IEEE, and Xin Luo[®], Senior Member, IEEE

Abstract-Robots facilitate a critical category of equipment to implement intelligent production. However, due to extensively inevitable factors like structural errors and gear tolerances, the positioning error of an industrial robot is several millimeters, therefore failing to fulfill the high-precision manufacturing requirements. To address the critical problem, this work develops a novel calibration algorithm that incorporates an unscented Kalman filter and a variable step-size Levenberg-Marquardt (UKF-VSLM) algorithm for efficient industrial robot calibration with the following twofold ideas: 1) developing a novel variable step-size Levenberg-Marquardt (VSLM) algorithm to address the local optimum issues encountered by a standard Levenberg-Marquardt (LM) algorithm and 2) incorporating an unscented Kalman filter (UKF) into the proposed VSLM algorithm to suppressing the measurement noises during the calibration process. Empirical studies on a HuShu Robotics (HSR) JR680 industrial robot demonstrate that compared with state-of-the-art calibration algorithms, the calibration accuracy of the developed UKF-VSLM is 19.51% higher than that of the most accurate LM algorithm measured by the maximum error. The empirical results strongly support the superior performance of the proposed algorithm in addressing robot calibration issues.

Index Terms— Absolute positioning accuracy, industrial robots, kinematic parameters, robot calibration, unscented Kalman filter (UKF), variable step-size Levenberg–Marquardt (VSLM).

I. INTRODUCTION

I NDUSTRIAL robots are the major equipment of advanced manufacture. The vigorous development of industrial robotics can help the fast establishment of advanced manufacture [1], [2], [3], [4], [5], which further promotes industrial upgrading to improve people's daily life. However, industrial robot applications commonly involve complex tasks with high precision requirements [5], [6], [7], [8], [9], [10]. Generally, a calibrated industrial robot enjoys its greatly high repetitive positioning accuracy, while the absolute

positioning error of an uncalibrated robot might reach several millimeters and thus fail the demands of high-precision offline programming and intelligent application [11], [15], [18]. Additionally, the error sources of industrial robots mainly contain robot kinematic and dynamic errors, where the kinematic parameter error yields about 90% of the total errors [11], [12], [13], [14], [15]. Hence, we mainly consider the error of robot kinematic parameters. Consequently, implementing its kinematic parameter calibration efficiently is a vital method to enhance the positioning accuracy of the robot [16], [17], [18], [19], [20].

Aiming at addressing the thorny issue of robot calibration, pioneer researchers have made various explorations [21], [22], [23], [24], [25]. Liu et al. [1] design a closed-loop kinematic calibration method with a six-point measuring device, which adopts the Levenberg-Marquardt (LM) algorithm to calibrate a UR10 robot. Xu et al. [2] propose an improved manta ray foraging optimization algorithm for calibrating a self-designed 6-DOF robot, which reduces the robot positioning error from 10.24 to 0.55 mm. Cao et al. [3] incorporate an extended Kalman filter (EKF) into an artificial neural network (ANN) with a butterfly and flower pollination algorithm for calibrating the Stewart platform, which achieves excellent calibration performance. Wang et al. [5] develop a beetle swarm optimizationincorporated multilayer neural network model for calibration. Experiments on a SIASUN SR210D robot manipulator demonstrate that this calibrator achieves fast convergence and high calibration accuracy. Chen and Zhan [4] develop an improved beetle swarm optimization algorithm to calibrate a KUKA KR500L340-2 robot, thereby obviously reducing its positioning error. The above-mentioned calibration methods all are able to improve the robot calibration accuracy. However, they frequently suffer from the issue of falling into the local optimum, which harms the calibration accuracy.

As analyzed in a prior study, there are extensive measurement noises in robot calibration, which results in this terrible phenomenon. Moreover, the stationary step size of an LM algorithm may also limit its optimization ability when seeking the optimal kinematic parameters. Motivated by the above discovery, this article proposes an efficient robot calibration algorithm based on an unscented Kalman filter (UKF) algorithm and a newly presented variable stepsize Levenberg–Marquardt (VSLM) algorithm. Specifically, the ideas of this work are threefold.

- Incorporating the variable step-size term into the learning scheme of an LM algorithm, thereby achieving a VSLM algorithm with high searching stability and computing efficiency.
- 2) Adopting a UKF to suppress the measurement noises.
- 3) Building a calibration algorithm via seamlessly cascading a UKF and a VSLM, which can efficiently discover the optimal kinematic parameters of the robot.

The major contributions of this work include the following.

- 1) This article proposes a novel VSLM algorithm with variable step size, which achieves better searching ability than a standard LM algorithm.
- A UKF-VSLM calibration algorithm is proposed to achieve efficient and accurate industrial robot calibration results.

TABLE I KINEMATIC PARAMETERS OF THE HSR JR680 ROBOT BEFORE CALIBRATION

Item <i>i</i>	$a_i/$	a _i /mm	d _i /mm	$ heta_i$ />
1	-90	250	653.5	0
2	0	900	0	-90
3	90	-205	0	180
4	-90	0	1030.2	0
5	90	0	0	90
6	0	0	200.6	0

- Detailed algorithm design and analysis for the developed UKF-VSLM calibrator have been provided, which provide essential guidance for researchers and practitioners.
- 4) Empirical studies on a HuShu Robotics (HSR) JR680 industrial robot demonstrate that compared with state-ofthe-art calibration algorithms, the calibration accuracy of the developed UKF-VSLM is 19.51% higher than that of the most accurate LM algorithm measured by the maximum error.

II. PROBLEM STATEMENT

First, this work discusses the kinematic model and error model for the industrial robot, and then the principle of calibration algorithm based on a drawstring displacement sensor is discussed. Furthermore, the adopted symbols are depicted in Nomenclature.

To accurately optimize the robot kinematic parameter errors, this work carefully gathers the robot position data [26], [27], [28], [29], [30]. Advanced measuring instruments like a laser tracker, a theodolite, and a vision device are either very expensive or lead to low calibration efficiency [31], [32], [33], [34], [35]. Meanwhile, they mostly require particular maintenance, which further restricts their industrial applications in real environments [36], [37], [38], [39], [40]. Hence, for simulating real industrial needs, we adopt a drawstring displacement sensor as the datagathering instrument [41], [42], [43], [44], [45]. It contains the virtues of high measurement accuracy and stability as well as convenience [45], [46], [47], [48], [49], [50].

Note that robot calibration has four parts: 1) kinematic modeling; 2) measuring the position of the end-effector; 3) the identification of kinematic parameters; and 4) kinematic parameter errors compensation [51], [52], [53], [54], [55]. The modeling step hugely affects the industrial robot positioning error. Recently, the popular kinematic model is the DH (Denavit and Hartenberg) model. Hence, we adopt it to build the robot kinematic model. For an HSR JR680 industrial robot with six degrees of freedom, its joint angles and initial DH parameters are depicted in Fig. 1 and Table I, respectively.

For the principle of the classical DH model [54], [55], [56], [57], [58], [59], [60], the kinematic transformation of its adjacent joints is given as

$$K_{i} = \begin{bmatrix} \cos \theta_{i} & -\sin \theta_{i} \cos \alpha_{i} & \sin \theta_{i} \sin \alpha_{i} & a_{i} \cos \theta_{i} \\ \sin \theta_{i} & \cos \theta_{i} \cos \alpha_{i} & -\cos \theta_{i} \sin \alpha_{i} & a_{i} \sin \theta_{i} \\ 0 & \sin \alpha_{i} & \cos \alpha_{i} & d_{i} \\ 0 & 0 & 0 & 1 \end{bmatrix}$$
(1)

Fig. 1. Joints of the HSR JR680 industrial robot.

where *K* is the link transformation matrix, a_i represents the link length, d_i is the link offset, θ_i is defined as the joint angle, α_i is given the link twist angle [61], [62], [63], [64], [65]. So, the transformation relationship from the robot base to its end-effector is written as

$$K_6^0 = K_1^0 K_2^1 K_3^2 K_4^3 K_5^4 K_6^5.$$
 (2)

To identify the DH parameters errors of the robot, the deviation of the robotic transformation matrix is calculated by

$$dK = K_R - K_6^0 \tag{3}$$

where dK represents the pose deviation of the robot and K_R is the actual pose of the robot. Based on (3), dK can be written as

$$dK_i = \frac{\partial K_i}{\partial \alpha_i} d\alpha_i + \frac{\partial K_i}{\partial a_i} da_i + \frac{\partial K_i}{\partial d_i} dd_i + \frac{\partial K_i}{\partial \theta_i} d\theta_i.$$
 (4)

Based on (3) and (4), the pose error of the robot is represented as

$$e = \begin{bmatrix} J_1 & J_2 & J_3 & J_4 \end{bmatrix} \begin{bmatrix} \Delta a \\ \Delta d \\ \Delta \alpha \\ \Delta \theta \end{bmatrix} = JX$$
(5)

where J represents the differential identification Jacobian matrix and X represents the errors of the DH parameters.

Based on the robot calibration principle [66], [67], [68], [69], [70], the error of cable length is approximately equal to the robot positioning error, thus yielding the following learning function:

$$f(X) = \min\left[\frac{1}{m}\sum_{i=1}^{m} (Z_i - Z'_i)^2\right]$$
(6)

where Z'_i and Z_i are the calculated cable length and measuring cable length, respectively, and *m* is the sampling point count.

Commonly, the nominal cable length can be calculated as

$$Z'_{i} = \sqrt{(P_{i} - P_{0})^{2}}.$$
(7)

Note that P_i represents the calculated position of the robot end-effector and P_0 is defined as the coordinate value of the fixed point.

In general, the robot error model is a highly nonlinear model with extensively complex factors [71], [72], [73], [74], [75], whose analytic solutions cannot be achieved via conventional optimization algorithms. In addition, there are extensive measurement noises during the calibration process, which has huge harm to the robot positioning accuracy. To deal with this thorny problem, we propose an efficient UKF-VSLM algorithm to calibrate the robot.

III. UKF-VSLM ALGORITHM

A. UKF Algorithm

To address the estimation issue in nonlinear systems, a UKF algorithm is proposed by researchers. It adopts an unscented transformation to sample state values, whose average value and covariance are calculated by some sigma points. Compared with the linearization of the nonlinear system by the EKF, the UKF algorithm makes a higher approximation. Moreover, the UKF algorithm has been widely utilized in electronics, medical science, aerospace, and other fields [12].

First, considering the principle of the UKF algorithm, the sigma vector is addressed by the unscented transformation. Then the posteriori sigma vector $X'_{i,k|k-1}$ and the posteriori measuring state $Y'_{i,k|k-1}$ are presented as

$$\begin{cases} X'_{i,k|k-1} = \Phi_k(X'_{i,k-1}) \\ Y'_{i,k|k-1} = H_k(X'_{i,k|k-1}). \end{cases}$$
(8)

Based on (8), we can achieve the covariance P_k^- and priori state \hat{x}_k^- , where W_i is the weight of sigma point *i*

$$\begin{cases} \hat{x}_{k}^{-} = \sum_{i=0}^{N+1} W_{i} X_{i,k|k-1}' \\ P_{k}^{-} = \sum_{i=0}^{N+1} W_{i} (X_{i,k|k-1}' - \hat{x}_{k}^{-}) (X_{i,k|k-1}' - \hat{x}_{k}^{-})^{T}. \end{cases}$$
(9)

Then the mean \hat{y} and covariance *S* of the observation model are written as

$$\begin{cases} \hat{y}_{k|k-1} = \sum_{i=0}^{N+1} W_i Y'_{i,k|k-1} \\ S_{k|k-1} = \sum_{i=0}^{N+1} W_i (Y'_{i,k|k-1} - \hat{y}_{k|k-1}) (Y'_{i,k|k-1} - \hat{y}_{k|k-1})^T. \end{cases}$$
(10)

Additionally, the Kalman gain ρ and the cross-covariance P_{xy} can be represented as

$$\begin{bmatrix} P_{xy,k|k-1} = \sum_{i=0}^{N+1} W_i (X'_{i,k|k-1} - \hat{x}_k^-) (Y'_{i,k|k-1} - \hat{y}_{k|k-1})^T, \\ \rho = P_{xy,k|k-1} S_{k|k-1}^{-1}. \end{bmatrix}$$
(11)

Lastly, the updating estimation of *X* and the covariance P_k are as follows:

$$\begin{cases} \hat{x}_k = \hat{x}_{k|k-1}^- + \rho (Y_k - \hat{y}_{k|k-1}) \\ P_k = P_{k|k-1}^- - \rho S_{k|k-1} \rho^T \end{cases}$$
(12)

where Y_k represents the current set of observations.

B. VSLM Algorithm

Considering the robot error identification model (5), if the identification coefficient matrix J is a full-rank matrix, then the least-squares solution of robot calibration is obtained as

$$X = \left(J^T J\right)^{-1} \cdot J^T \cdot E \tag{13}$$

where $E = Z_i - Z'_i$.

However, the robot error model has redundant parameters, making J frequently suffers from singulars. Hence, the LM algorithm is adopted to address this issue, leading to the following solution:

$$X = \left(J^T J + \lambda I\right)^{-1} \cdot J^T \cdot E \tag{14}$$

where λ represents the learning rate and *I* represents the unit matrix. However, from (13), we see that the update of *X* is conducted with a stationary step size of one, which limits its searching ability. To address this issue, we incorporate a variable step size into its update rule as

$$\begin{cases} X = \left(J^T J + \lambda I\right)^{-1} \cdot J^T \cdot E \cdot \delta_t \\ \delta_{t+1} = \delta_t \cdot \mu \end{cases}$$
(15)

where δ is the step size of searching commonly set at 0.8, and the decaying constant μ lies in the (0, 1) interval and is commonly set at 0.95. Note that with (15), the step size keeps decreasing as the iteration count increases, thereby leading to the following effects: 1) at the early stage of objective minimization, the step size is large to make the model fast approach an equilibrium point and 2) as the training process continues, the step size gradually decreases to implement finetuning of the calibration model.

To make the convergence analysis of the developed VSLM algorithm, the meaningful theorem is presented as follows.

Theorem 1: As f'(X) = 0, if the initial kinematic parameters X_0 and coefficient matrix J_k developed by the Newton-like algorithm can satisfy the following equation:

$$\begin{cases} \|J_0^{-1}\| \le \beta \\ \|J_0^{-1}f'(X_0)\| \le \kappa \\ \|J_M - J_N\| \le \tau \|X_M - X_N\| \quad \forall X_M, X_N \in U(X_0, \xi). \end{cases}$$
(16)

If the convergence factor g satisfies the following conditions:

$$\begin{cases} g = \beta \kappa \tau \leq \frac{1}{2} \\ \xi \geq 1 - \frac{\sqrt{1 - 2g}}{g\kappa} \end{cases}$$
(17)

where β , κ , and τ are the real numbers. Consequently, the equation f'(X) = 0 can achieve solutions in the range $U(X_0, \xi)$. Note that Jacobian matrix J_k should satisfy the Lipschitz condition in Theorem 1.

Proof of Theorem 1: The definition of a quadratic optimal function is given as

$$h(x) = \frac{1}{2}\tau x^2 - \frac{1}{\beta}x + \frac{\kappa}{\beta} = 0.$$
 (18)

Let h(x) = 0, we achieve two roots

$$x^* = \frac{1 - \sqrt{1 - 2\beta\tau\kappa}}{\beta\tau}$$
$$x^{**} = \frac{1 + \sqrt{1 - 2\beta\tau\kappa}}{\beta\tau}.$$
 (19)

Based on (17), (19) can be reformulated as

$$x^{*} = \frac{1 - \sqrt{1 - 2g}}{g} \kappa$$
$$x^{**} = \frac{1 + \sqrt{1 - 2g}}{g} \kappa.$$
 (20)

Note that x_k is the solution of the Newton iteration sequence, and we have

$$x_{k+1} = x_k - \frac{h(x_k)}{h'(x_k)}.$$
(21)

According to [67] and [70], we can easily prove that $x_k \rightarrow x^*$. Then we should prove the following inequality:

$$\left\|\Delta X^* - \Delta X_k\right\| \le x^* - x_k \tag{22}$$

where ΔX the variation of kinematic parameters. According to [69], we can prove that

$$\|\Delta X_M - \Delta X_N\| \le x_M - x_N \quad \forall M, N \in \mathbb{R}^*$$
(23)

where R^* is a positive integer. Due to the convergence of $\{x_k\}$, we can easily prove that $\{X_k\}$ is a Cauchy convergence sequence. Then we can obtain that the limits of the sequence $\{X_k\}$ are X^* .

Let $M \to \infty$, we achieve that $\|\Delta X^* - \Delta X_k\| \le x^* - x_k$.

Note that $\Delta X^* = 0$ and the continuity of f'(X), we can achieve that $J^* = 0$. Therefore, X^* is the solution of equation f'(X) = 0. Most importantly, it is very vital to present the convergence analysis of the VSLM algorithm, which provides a theoretical basis for the proposed algorithm. Our theoretical proof is based on a Newton-like method, which also gives us some ideas to improve the algorithm in the future.

C. Calibration Process of a UKF-VSLM Algorithm

As discussed in Sections III-A and III-B, the UKF-VSLM algorithm consists of two parts: 1) adopting a UKF to address the thorny noises and 2)establishing a new VSLM algorithm to further search the optimal kinematic parameters of the robot. The flowchart of the developed UKF-VSLM algorithm is depicted in Fig. 2.

D. Algorithm Design and Analysis

According to the analysis of the developed Algorithm 1: UKF-VSLM, its time cost can be divided into three parts.

1) Initialization

$$T_{11} = \Theta(r) \tag{24}$$

where *r* is the dimension of X_0 .

2) The time cost of the UKF step is

$$T_{12} = \Theta(T_3 \times M). \tag{25}$$

Algorithm 1 UKF-VSLM **Input:** $T_3, X_0, \{q_{i,1}, q_{i,2}, \ldots, q_{i,6}\} \{Y_1, Y_2, \ldots, Y_{|M|}\}$ Operation Cost /* Initialization */ 1 Initialize $T_3, M, \delta, \mu, \lambda, T_9, W_i$ T_{11} 2 Initialize: $X'_{i,k-1} = X_0$ /* Training Starts */ /* UKF-Step */ 3 for k = 1 to $|T_3|$ do set $P_{(0)k}$ random number 4 5 set $\rho_{(0)k}$ zero for i = 1 to |M| do 6 Update $X'_{i,k|k-1}$, $Y'_{i,k|k-1}$ with (8) 7 Calculate J_k with (5) 8 Compute P_k^- , \hat{x}_k^- based on (9) T_{12} 9 Calculating $\hat{y}_{k|k-1}$, $S_{k|k-1}$ via (10) 10 Updating $P_{xy,k|k-1}$, ρ based on (11) 11 Calculating \hat{x}_k , P_k with (12) 12 end for 13 14 end for 15 $x_{ukf} = \hat{x}_k$ /* VSLM-Step */ 16 for t = 1 to $|T_9| T_{13}$ do $set X_0 = x_{ukf}$ 17 for i = 1 to |M| do 18 Updating δ_{t+1} , X based on (15) 19 end for 20 21 end for /* Operation Ending */

Output: X

Fig. 2. Algorithm flowchart of robot error identification.

3) The time cost of the VSLM step is

$$T_{13} = \Theta(T_9 \times M). \tag{26}$$

Moreover, we commonly obtain $r \ll T_1 \times M$ in robot calibration, (24) is far less than $\Theta(T_1 \times M)$. Hence, the overall time cost of Algorithm UKF-VSLM is given as

$$T_1 = T_{11} + T_{12} + T_{13} \approx \Theta((T_3 + T_9) \times M).$$
 (27)

Additionally, Algorithm 1 shows the detailed algorithm design of our proposed algorithm. T_3 and T_9 represent the maximum number of calculations for the UKF algorithm and VSLM algorithm, respectively. *M* represents the number of samples and *X* is the errors of DH parameters. Due to the measuring noises in robot calibration, the UKF algorithm is adopted to address this issue. Then the obtained parameter identification results by the UKF algorithm are taken as the input of the VSLM algorithm. Lastly, the optimal kinematic parameters are calculated by the VSLM algorithm [73], [74], [75], [76], [77], [78].

IV. EXPERIMENTAL RESULTS

A. General Settings

1) Evaluation Metrics: In this part, the root mean squared error (RMSE), standard deviation (STD), and the maximum error (MAX) are utilized as the evaluation metrics

MAX = max
$$\left\{ \sqrt{\left(Z_{i} - Z_{i}'\right)^{2}} \right\}, \quad i = 1, 2, ..., m$$

STD = $\frac{1}{m} \sum_{i=1}^{m} \sqrt{\left(Z_{i} - Z_{i}'\right)^{2}}$
RMSE = $\sqrt{\frac{1}{m} \sum_{i=1}^{m} \left(Z_{i} - Z_{i}'\right)^{2}}.$ (28)

2) *Experimental Datasets:* In this section, we collect three public datasets for our experiments, whose details are as follows.

- D1: HSR-RobotCali. We collect 2000 samples on an HSR JR680 industrial robot, which are evenly distributed in the whole robot workspace. Then, Table II shows five samples of this dataset, each sample has six rotation angles and the measuring cable length. Lastly, we adopt the proposed method to accurately identify robot kinematic parameter errors. Moreover, this dataset is publicly available on the website.¹
- 2) D2: RobotCali. It is collected by an ABB robot [75]. It has 1042 samples, each of which consists of the cable length and six rotation angles.¹ To conduct the robot calibration experiments, 120 sampling points are randomly selected from RobotCali.
- 3) D3: The public robot position dataset, which is gathered on the Universal Robot [65]. It contains 16811 samples, which consist of four position datasets: A, B, C, and D. In addition, we choose 200 samples from A to conduct experiments.

Each dataset is implemented in 80%–20% train test settings.

Item	Specification
Supply voltage	AC220V 50Hz
Input resistance	5K
Pulse frequency	≪500K
Magnification range	$0.000{\sim}999.999$
Display range	-199999~999999
Pulse width	2us
Operating temperature	-10°C~50°C

3) Experimental Platform: To accurately calibrate the robot, we design an experimental platform as shown in Fig. 3(a). The HSR JR680 industrial robot produced by HuaShu robot company is used as an experimental subject. Then the position of the robotic end-effector is measured by a drawstring displacement sensor. Additionally, a drawstring displacement indicator is adopted for displaying the value of cable length. We have added the details of the utilized hardware in Tables III-V, including the drawstring displacement sensor, the drawstring displacement indicator, and HSR JR680 industrial robot. Moreover, MATLAB software is applied in dealing with this data and outputting the calibrated kinematic parameters.

The data-gathering process is from sampling points 1-4, four diversified samples are gathered in different positions, which are adopted to calculate the robot positioning error. (a) Robot measuring pose for sampling point 1. (b) Robot measuring pose for sampling point 2. (c) Robot measuring pose for sampling point 3. (d) Robot measuring pose for sampling point 4.

4) Experimental Process: In the robot calibration process, to collect accurate samples, the selection of measurement points should cover the workspace of the HSR JR680 industrial robot. Fig. 4 shows the data-gathering process of four sampling points. In this work, 120 position points are chosen in the motion range of an HSR JR680 industrial robot, then a drawstring displacement sensor is utilized to measure the position of these sampling points. Furthermore, a data acquisition program is developed based on the LabVIEW software, which can conveniently record sample information. The developed program is shown in Fig. 3(b).

In this experiment, a training dataset with 100 samples is utilized to calculate the robot position error, then the remaining 20 samples are utilized as comparison data. After calibration, we compare the calibration accuracy of some state-of-theart calibration algorithms to validate the correctness of the developed algorithm.

TABLE VI Compared Calibration Algorithms

Algorithm	Description
	The conventional extended Kalman filter is adopted to
M1	address the measuring noise in calibration process by
	Jiang <i>et al</i> . [9].
	The beetle antennae search algorithm is proposed by
M2	Khan et al. [6], which is adopted to optimize robot
	trajectory.
	The unscented Kalman filter is developed in [12], which
M3	is adopted to reckon the errors of the robotic kinematic
	parameters.
	The particle swarm optimization algorithm is proposed
M4	by Lee et al. [37], which is also utilized to optimize
	robotic kinematic parameters.
	The Radial basis function neural network (RBF)
M5	proposed in [15], which is adopted to estimate the
	positional errors of target positions.
	The Levenberg-Marquardt (LM) algorithm proposed in
M6	[1], which is utilized to calibrate the kinematic
	parameters of the UR10 robot.
M7	The differential evolution algorithm is proposed by Zhou
	<i>et al.</i> [17], which can also accurately calibrate the robot.
	The variable step-size Levenberg-Marquardt (VSLM)
M8	algorithm, which enhances the calibration accuracy of
	LM algorithm by adding the variable step-size term.
M9	The proposed UKF-VSLM algorithm in this work, which
	can enhance the robot calibration performance.

M9	$\Theta((T_3+T_9)\times M)$

B. Comparison With Advanced Calibration Algorithms

In this part, we compare the calibration performance of the developed algorithm against several advanced algorithms. Table VI summarizes the details of all test algorithms. Table VII lists the computational complexity analyses of compared algorithms, which rely on the maximum number of iterations and the number of samples. T_1-T_9 are the maximum number of calculations for M1-M9, respectively. M denotes the number of samples. Table VIII lists the experimental results of various algorithms, then Table IX shows the iteration time cost of algorithms M1–M9. In addition, Table X shows the experimental results of the Wilcoxon signed-ranks test on RMSE/STD/MAX of Table VIII, and Table XI presents the experimental results of the Wilcoxon signed-ranks test on total time cost of Table IX. Moreover, Table XII shows the parameter errors identified by M9 on D1–D3, and Table XIII lists the parameter errors identified by M1-M9 on D1.

Fig. 5 shows the calibration results of various algorithms. Fig. 6 shows the training curves and the number of iterations rounds. Fig. 7 shows the robot calibration error of various algorithms on D1. Based on the above analysis, we summarize as follows.

- Compared with state-of-the-art calibration algorithms, the proposed UKF-VSLM algorithm has the best calibration accuracy. As shown in Fig. 5(a) and Table VIII, M9 achieves the MAX error at 0.99 mm, which is, respectively, 38.89% lower than M1's 1.62 mm, 44.07% lower than M2's 1.77 mm, 35.71% lower than M3's 1.54 mm, 24.42% lower than M4's 1.31 mm, 48.70% lower than M5's 1.93 mm, 19.51% lower than M6's 1.23 mm, 34.43% lower than M7's 1.51 mm, 13.91% lower than M8's 1.15 mm on D1. Similar results are also encountered on D1–D3 when adopting RMSE and STD as the evaluation metrics, as shown in Figs. 5(a)–(c) and Table VIII.
- 2) Incorporating variable step-size terms into the LM algorithm can enhance computational efficiency. From Fig. 6(a) and (b), M8's converge rate is faster than that of M6. It only takes 20 iterations to reach the termination condition. We also obtain similar results on D2–D3, as illustrated in Table IX.
- 3) The UKF-VSLM's time cost is higher than that of the most efficient calibration algorithms. As depicted in Fig. 6(c) and Table IX, M9's time cost is lower than that of M2, M4, M6, and M7, but generally higher than that of M1, M3, M5, and M8. This is because the UKF-VSLM algorithm relies on a cascade structure, its UKF and VSLM components should be trained in a serial way for identifying robotic kinematic parameter errors. Note that such time costs can be greatly reduced by implementing efficient model parallelization with the help of GPU or other parallelization computing frameworks.
- 4) The proposed UKF-VSLM algorithm obtains the best calibration performance among state-of-theart calibration algorithms. To accurately calibrate the robot, we adopt M9 to identify the kinematic parameters. Table XII shows the parameter errors identified by M9 on D1-D3, which can be adopted to compensate for the robot's kinematic parameters. Then, we utilize the calibrated kinematic parameters to calculate the M9's calibration accuracy on D1-D3. Moreover, Table XIII lists the parameter errors identified by M1–M9 on D1, which can be adopted to compensate kinematic parameters of the HSR JR680 industrial robot. Additionally, 2000 measurement points are obtained on an HSR JR680 industrial robot. After finishing the robot calibration, we compare the calibration results of these algorithms on D1, which is shown in Fig. 7. From the results, the robot positioning error is significantly reduced after calibration. M9 has the best calibration performance among M1-M8. Similar experiments are achieved on D2–D3, as shown in Table VIII.
- 5) The accuracy gain of the proposed UKF-VSLM algorithm is significant. We adopt the Wilcoxon signedranks test to check the effectiveness of the proposed algorithm in terms of calibration accuracy and total time cost when compared with other calibration algorithms, which is shown in Tables X and XI. Moreover, the Wilcoxon signed-ranks test consists of R+, R-, and *p*-value. The higher R+ represents the higher calibration accuracy and lower time cost, and the *p*-value is at

the significance level. On the one hand, compared with M1–M8, M9 has the highest calibration accuracy. On the other hand, M9 has a higher significance than M4, M6, and M7 in terms of time cost. However, the unacceptable hypothesis emerges on M1–M3, M5, and M8, the reasons for which are given in Section IV-B.

C. Summary

From the above extensive experimental results, we can achieve the following summaries.

 Generally speaking, laser tracker, theodolite, and vision devices are adopted for measuring the robot's position, which have high measurement accuracy. However, they have extremely complex operations and expensive prices. Meanwhile, to operate conveniently the instruments, we spend extensive time and energy training

some professional engineers. Moreover, it is necessary to deal with the complex conversion operation between the robotic coordinate system and the coordinate system of measuring devices. To address this issue, we develop a measurement scheme with a drawstring displacement sensor, which has the advantages of good stability, convenient handling, small mass, low cost, and high measurement accuracy.

- 2) To improve the searching ability of the LM algorithm, the variable step-size term is incorporated into its learning rule. The proposed VSLM algorithm has high computational efficiency and calibration accuracy.
- 3) Based on the VSLM algorithm, we propose the UKF-VSLM algorithm to calibrate the robot. First, the UKF algorithm is employed to reduce the influence of measuring noises, then the VSLM algorithm is applied to further optimize the robot positioning error. Furthermore, it achieves best calibration accuracy than other advanced algorithms.
- 4) For the developed measurement scheme and the proposed calibration algorithm, we design the detailed experimental platform for robot calibration and complete its own assembly. Meanwhile, the software for this experiment is developed, which implements the proposed calibration algorithm. Last, the feasibility of the developed algorithm is verified by numerous experimental results.

V. CONCLUSION

To achieve high calibration accuracy, this work proposes a novel calibration algorithm combining a UKF algorithm and a VSLM algorithm. First, a UKF algorithm is adopted to optimize DH parameter errors, which addresses the issue of measuring noise in the calibration process. To improve the searching ability of the LM algorithm, a variable step-size term is incorporated into its evaluation rule. Then we propose a VSLM algorithm, which is utilized to further calibrate the robot position errors. Furthermore, the experimental results demonstrate that the developed UKF-VSLM algorithm achieves best calibration accuracy than other advanced algorithms. Therefore, the virtues of the proposed calibration method are as follows.

- 1) The UKF algorithm successfully addresses the issue of measuring noise in the calibration process.
- 2) The proposed VSLM algorithm can accelerate the convergence rate of the LM algorithm.
- 3) Based on the VSLM algorithm, the UKF-VSLM algorithm is proposed in this work, whose calibration accuracy is higher than other advanced algorithms.
- 4) The proposed calibration method with a drawstring displacement sensor significantly reduces the cost of the measurement instrument.

However, the proposed calibration method also has several defects.

- 1) In general, the proposed UKF-VSLM algorithm has high calibration accuracy. However, it suffers from computational efficiency loss when compared with the single UKF or VSLM algorithm.
- 2) This utilized calibration algorithm only considers the effect of geometric factors on robot positioning error, while it ignores the nongeometric factors, such as gear backlash and exterior load that may cause degeneration in robot positioning accuracy.
- 3) The proposed calibration algorithm is based on offline calibration calling for stopping the robot when performing the calibration, which affects the real industrial production process.

Aiming at addressing the above-mentioned issues, the future work is as follows.

- 1) We plan to design a model parallelization with the help of GPU or other parallelization computing frameworks for accelerating the proposed UKF-VSLM algorithm.
- 2) Nongeometric factors will be taken into account in modeling to obtain more accurate error sources.
- 3) Vision is a simple measurement method [76], which is able to conduct online calibration without stopping the robot. It also has the virtues of low cost, high accuracy, and high security. Therefore, we will develop a novel calibration method based on visual measurement equipment.
- 4) A neural network is an intelligent algorithm with strong robustness, independent learning ability, and high self-adaptability [2], [4], [78], which can approximate any continuous nonlinear function. Hence, it is also appropriate for addressing the issue of robot calibration. In a word, we plan to develop a state-of-the-art calibration algorithm with a neural network to improve robot positioning accuracy.
- 5) With the complexity of the robot application environment, higher industrial requirements are put forward for the robot. To satisfy the complex measurement environment, we plan to design a new measurement method with various spatial constraints, like plane constraints and point constraints.

Zhibin Li received the B.S. degree in measuring and control technology and instrumentations and the M.E. degree in instrument science and technology from Southwest Petroleum University, Chengdu, China, in 2014 and 2018, respectively. He is currently pursuing the Ph.D. degree in computer science with the Chongqing University of Posts and Telecommunications United training by the Chongqing Institute of Green and Intelligent Technology, Chinese Academy of Sciences, Chongqing, China.

His research interests include robot calibration, big data analysis, and algorithm design for large-scale data applications.

Shuai Li (Senior Member, IEEE) received the B.E. degree in precision mechanical engineering from the Hefei University of Technology, Hefei, China, in 2005, the M.E. degree in automatic control engineering from the University of Science and Technology of China, Hefei, in 2008, and the Ph.D. degree in electrical and computer engineering from the Stevens Institute of Technology, Hoboken, NJ, USA, in 2014.

He is currently a Full Professor with the Faculty of Information Technology and Electrical Engineering,

University of Oulu, Oulu, Finland. His current research interests include dynamic neural networks, robotics, machine learning, and autonomous systems.

Xin Luo (Senior Member, IEEE) received the B.S. degree in computer science from the University of Electronic Science and Technology of China, Chengdu, China, in 2005, and the Ph.D. degree in computer science from Beihang University, Beijing, China, in 2011.

He is currently a Professor of data science and computational intelligence with the College of Computer and Information Science, Southwest University, Chongqing, China. He has authored or coauthored over 200 articles (including over 100 IEEE

Transactions articles) in the areas of his interests. His research interests include big data analysis and graph learning.

Dr. Luo was a recipient of the Outstanding Associate Editor Award from IEEE/CAA JOURNAL OF AUTOMATICA SINICA in 2020. He is also serving as a Deputy-Editor-in-Chief for IEEE/CAA JOURNAL OF AUTOMATICA SINICA and an Associate Editor for IEEE TRANSACTIONS ON NEURAL NETWORKS AND LEARNING SYSTEMS.
