ABSTRACT Automatic recognition of illegal substations is of great importance, since most of the leakage electricity in Turkey is due to the use of these substations in agricultural fields. One of the most effective ways to detect illegal substations is to employ remote sensing images and machine learning techniques together. Because, thanks to remote sensing images, it is possible to analyze illegal substations on huge agricultural lands in a short time. In this study, illegal substations on the agricultural fields in the southeast Anatolian region, which is one of the regions where leakage electricity are most common, have been detected with the aid of Landsat-8 OLI images and machine learning algorithm. The proposed study has been carried out in several stages, respectively. In the first stage, the locations of 42 substations and 21 non-substation objects on the pilot area have been recorded with the help of GPS and these coordinates have been later transferred to the Landsat-8 OLI image dated on 14 June 2019. In the second stage, an image analysis has been performed by calculating the spectral band parameters from the Landsat-8 OLI images. In the next stage, relationships among illegal substations and non-substation objects have been set by utilizing the statistical metrics of obtained spectral band parameters. In the last stage, by utilizing LSTM (Long Short-Term Memory) method, which is a recurrent neural network model that has gained popularity in both remote sensing and various scientific disciplines in recent years and the Logit-Boost method, which is one of the popular boosting machine learning algorithms, automatic recognition of substations has been performed with an average accuracy of 88.89% for Logit-Boost method and 84.21% for LSTM method. It is notable from this study that the Logit-Boost Algorithm yields more proficient results than the LSTM model.

INDEX TERMS Substation recognition, image analysis, landsat-8, Logit-Boost algorithm, LSTM.

I. INTRODUCTION

Object identification with the help of remote sensing images is a fundamental challenge in the field of satellite imaging and their analysis. However, object detection has gained great attention in recent years and plays an important role in a wide

The associate editor coordinating the review of this manuscript and approving it for publication was Jeon Gwanggil.

range of applications [1]. Identification of objects on large areas with traditional methods and modern measurement techniques requires a lot of expense, time and labor intensity [2]. These difficulties in determining objects over the lands can be overcome by employing remote sensing technologies.

In this context, with the recent development of medium or high spatial resolution satellite images and the easy production of spatial and spectral information, less costly results

can be obtained in a shorter time on large areas without requiring much workload [3]. In the literature, many studies have been carried out using remote sensing data. These studies are generally discussed under two main headings as active (Sentinel-1, Radarsat-1, Radarsat-2, etc...) and passive (Sentinel-2, Landsat-8, MODIS, etc...) systems. Some of the most studies using passive remote sensing systems with image processing or machine learning techniques are summarized as follows.

Acar and Altun proposed a system in order to classify agricultural crops (Lentil and Wheat) by utilizing Support Vector Machine (SVM) technique and Landsat-8 Normalized Difference Vegetation Index parameters. As a result, a high overall accuracy was observed for crop classification [4]. Balogun et al. employed multispectral Landsat 8-OLI image and machine learning models (Support Vector Machine and Random Forest) to determine the effects of oil spills over coastal wetland and vegetation. Moreover, they monitored the recovery pattern of polluted wetland and vegetation in a coastal city, Malaysia [5]. Sekandari et al. recommended an approach in order to identify Zn-Pb mineralization in the Kashmar–Kerman Tectonic Zone and the Central Iranian Terrane by utilizing different satellite images (Sentinel-2, ASTER, Landsat-8 and WorldView-3) and Principal Component Analysis (PCA) based fuzzy logic modeling. The results indicated that spectral data obtained from multi-sensor remote sensing images can be widely employed to generate remote sensing-based probability maps for the research of Pb-Zn mineralization in many metallogenic provinces around the worldwide [6]. Vanhellemont investigated the land and water surface temperature by employing the performances of the Thermal Infrared Sensor (TIRS) single-band reuptakes in Landsat-8. As a result, a very temporal terrain method was demonstrated based on images obtained from the Landsat-8 and it was determined that it would be possible to provide precise absolute surface temperature [7]. Beiranvand Pour et al. proposed a system for mineral prospecting and mapping of hydrothermal alteration in the Inglefield Land, Northwest Greenland with the aid of various satellite images (ASTER, Landsat-8 and WorldView-3) and image processing techniques (Directed Principal Components Analysis, Linear Spectral Unmixing, Adaptive Coherence Estimator). The result showed that the differentiation of lithological units and zones include high concentration of clay minerals, iron oxides/hydroxide in the Inglefield Mobile Belt were accomplished by utilizing Landsat-8 image at the regional scale [8]. Golhani et al. suggested a system in order to detect orange spotting disease in oil palm by employing Red Edge and four spectral indices (simple ratio, red edge normalized difference vegetation index, two-band enhanced vegetation index 2 and chlorophyll index red edge). Moreover, they implemented multilayer perceptron neural network to build a nonlinear correlation among selected each spectral index and spectral bands. As a result, a highest correlation was observed between two-band enhanced vegetation index 2 and

spectral bands [9]. Fan et al. utilized Landsat-8 Operational Land Imager (OLI) Surface Reflection (SR), Visible Infrared Imaging Radiometer Suite and MODIS methods to detect earthquake damage areas. The data in the methods were applied to the Nepal earthquake with a magnitude of 7.8 in 2015 and they determined that there was not much difference between the obtained results and the estimated damaged pixels [10]. He et al. employed Landsat-8 satellite data to classify the effect of temperature on improving or reducing land surface temperature in Shenyang, China, at seven temperature levels and evaluated the relationship between land covers and their use [11]. Fang et al. compared deep learning methods and traditional machine learning methods using convolutional neural network (CNN)-based Landsat-8 satellite images to identify man-made global reservoirs [12]. Kuhn et al. compared Landsat-8 and Sentinel-2 reflectance products on rivers to indicate the relationship between satellite recovery on rivers, absorption and scattering properties of river water with remote sensing reflection [13]. Lamqadem et al. proposed an approach for mapping the amount of desertification in middle Draa Valley, Morocco by utilizing Spectral Index Techniques and Sentinel-2 image. The result showed that the proposed system is effective for mapping desertification with high accuracy [14]. Sameen et al. recommended a system for classifying aerial photographs into seven classes (grassland, road, building, waterbody, barren land, dense vegetation and shadow) with the help of convolutional neural network. Their proposed work demonstrated that CNN-based approaches can be utilized efficiently for land cover classification using aerial photographs [15]. Man et al. examined seven land classes utilizing high spatial resolution Landsat-8 satellite images by creating time series composite images from five supervised classifiers and using merging techniques to obtain maps of land cover types. As a result, they found that the resulting composite images were 20% more successful than the first images [16]. Arslan applied different image processing techniques (such as minimum noise fraction, convolution filters) to Landsat-8 bands in the detection of oil spill areas formed when a ship ran aground in Ildır Bay, İzmir. Finally, they obtained successful results by analyzing oil spill areas with the location of the ship [17]. Wang et al. analyzed radiation anomalies in a Gaussian Mixture Model with a new ship object detection method in the ocean using Landsat-8 satellite imagery as the long wavelength infrared band. As a result, they found the ship detection accuracy of this method with higher recall, unlike other classical methods [18]. Barnes and Hu determined an underwater coral reef area longer than 15 km using Landsat-8 satellite data for island construction in the South China Sea between 2013 and 2015, and evaluated water turbidity using MODIS data [19]. Avdan and Jovanovska developed a new algorithm using Landsat-8 thermal infrared sensor Band 10 data on land surface temperature. Then, to determine the accuracy of this algorithm, they compared the temperatures near the land surface and the air and found that the deviation was low [20]. Wieland

and Pittore evaluated the effect of Landsat-8 satellite data on SVM performance to define settlement type classification and urban building types based on the images of 43 settlements in Central Asia. As a result, they stated that these data used were sufficient and satisfactory for the classification tasks [21]. Jagalingam et al. determined bathymetry mapping by utilizing the blue and green bands of the Landsat-8 satellite due to open and free access to detect the bathymetry of the coasts in India and a good correlation was obtained between the results obtained and the hydrographic sounding values [22]. Acar tried to detect the EDTs on agricultural lands in Diyarbakir by using the Sentinel-1 SAR satellite data by machine learning method. He used ELM (Extreme Machine Learning) in his study and achieved an accuracy rate of 85.47% [23].

In this study, an image analysis has been performed by calculating the spectral band parameters from the Landsat-8 OLI images and relationships among substations and non-substation objects have been set by utilizing the statistical metrics of obtained spectral band parameters. Moreover, one of the most popular boosting algorithms and LSTM method have been employed in order to recognize illegal substations.

This study has two main contributions. One of these contributions is that a comparative image analysis has been performed by calculating the spectral band parameters from the substations and non-substation objects thanks to the statistical metrics of obtained Landsat-8 OLI spectral band parameters. Another contribution is that illegal substations in agricultural fields, which cause huge energy losses in Turkey, have been recognized automatically with the help of feature vectors to be created from the Landsat-8 OLI spectral band parameters, Logit-Boost Algorithm and LSTM.

The rest of the manuscript is organized as follows: the image pre-processing steps is detailed in Section II. Afterward, the experimental results on determining of the spectral band parameters are presented in Section III. A comprehensive discussion is given in Section IV. Finally, the proposed approach is summed up in Section V.

II. MATERIALS AND METHODS
A. THE EXPERIMENTAL AREA
In this study, the area where the substations and non-substation objects are located within the boundaries of Sason district of Batman province was chosen as the pilot region. The location of the experimental area and different samples (the dots in the satellite image) in this area are shown in Fig.1.

B. LANDSAT-8 OLI DATA ACQUISITION
Landsat-8 was launched on February 4, 2013 from Vandenberg Air Force Base, California. In this study, one LANDSAT/LC08/C01/T1 (Landsat 8, Collection 1, Tier 1) OLI satellite image courtesy of the U.S. Geological Survey belonging to 14 June 2019 was obtained by employing google

FIGURE 1. The position of the experimental area with the different substations (red points) and non-substation (yellow points) samples.

FIGURE 2. The color Landsat-8 OLI image obtained covering the study area.

earth engine code editor platform (https:// code. earthengine. google. com). Google Earth Engine is a cloud-based platform that performs it effortless to access high-performance computing facilities for processing numerous wide geospatial datasets [24]. The color image obtained by combining three different bands (Band 2+ Band 3+ Band 4) of the Landsat-8 OLI image covering the study area is shown in Fig. 2.

C. GROUND DATA COLLECTION
At this stage, the geographical coordinates of 42 different substations and 21 non-substations were recorded with the help of GPS device and then these data were imported to LANDSAT/LC08/C01/T1 OLI image with the aid of Google earth engine code editor as shown in Fig. 3.

D. FEATURE EXTRACTION FROM LANDSAT-8 OLI IMAGE
The Landsat-8 OLI data is the atmospherically corrected surface reflectance from the Landsat 8 OLI/TIRS sensors. This image includes 9 spectral bands which are 2 thermal infrared (TIR) bands, 2 short-wave infrared (SWIR) bands and 5 visible and near-infrared (VNIR) bands. The pixel resolution for Landsat-8 OLI Image is 30 m. The detailed information about the Landsat-8 OLI spectral band parameters are given in Table 1 [25].
FIGURE 3. Importing of the geographical coordinates of 42 different substations (red points) and 21 non-substations (yellow points) into the color Landsat-8 OLI image.

TABLE 1. Landsat-8 OLI spectral band parameters.

Spectral Bands	Wavelengths (μm)	Description
B1	435-451	Ultra Blue
B2	452-512	Blue
B3	533-590	Green
B4	636-673	Red
B5	851-879	Near Infrared
B6	1566-1651	Shortwave Infrared 1
B7	2107-2294	Shortwave Infrared 2

At this stage, the pixel values of the substation and non-substation samples corresponding to seven different spectral bands (B1-B7) of the Landsat-8 OLI data were calculated. However, (B10- B11) spectral bands were not evaluated because they are obtained using the Landsat 8 TIRS sensor. Consequently, feature vectors of seven-unit lengths were created for each sample point and this procedure is given in detail in the section III.

E. LOGIT-BOOST ALGORITHM

Logit-Boost is one of the popular boosting algorithms in machine learning and it is formulated by Jerome Friedman, Trevor Hastie, and Robert Tibshirani. This algorithm can be derived from the Ada-Boost algorithm because both are similar in the point of performing an additive logistic regression. The difference between them is that Ada-Boost diminishes exponential loss, while Logit-Boost reduces logistic loss. Moreover, the Logit-Boost algorithm is more convenient in order to handle the noisy data on the widely employed Ada-boost algorithm [26]. The Logit-Boost algorithm includes the following stages, respectively.

❖ Assume that input dataset contains N samples with input number of iterations K

$$N = \{(x_1, y_1), (x_2, y_2), \ldots, (x_i, y_i)\} \quad i = 1, 2, \ldots, N \quad (1)$$

Here, x_i and y_i represent input feature vectors and target, respectively.

FIGURE 4. The schematic of long short-term memory.

❖ Start the weights $w_i = \frac{1}{N}$, probabilities estimates $P(x_i) = \frac{1}{2}$ and initialize committee function $F(x) = 0$.

❖ Compute weights (w_i) and working response (z_i) by repeating for $k = 1, 2, \ldots, K$

$$w_i = P(x_i)(1 - P(x_i)) \quad (2)$$

$$z_i = \frac{y_i - P(x_i)}{P(x_i)(1 - P(x_i))} \quad (3)$$

❖ Fit $Fk(x)$ with a weighted least squares regression from z_i to x_i by employing w_i and then update the functions as indicated in Equation-4 and Equation-5.

$$F(x) \leftarrow F(x) + \frac{1}{2}Fk(x) \quad (4)$$

$$p(x) \leftarrow \frac{e^{F(x)}}{e^{-F(x)} + e^{F(x)}} \quad (5)$$

❖ Finally, the output of classifier becomes:

$$sign[F(x)] = sign\left[\sum_{k=1}^{K} Fk(x)\right] \quad (6)$$

Here, $sign[F(x)]$ has two output classes as shown in Equation-7.

$$sign[F(x)] = \begin{cases} -1 & if \ F(x) \geq 0 \\ +1 & if \ F(x) < 0 \end{cases} \quad (7)$$

F. LSTM METHOD

The LSTM neural network is a variant of the Recurrent Neural Networks (RNN) [27]. Compared to RNN, LSTM can handle both long-term dependence problems and reduce the possibility of gradient disappearance [28].

The core concept of LSTM is the cell state and the gate structure, cell states can convey information and overcome the effects of short-term memory. The LSTM has three types of gate structures: input, forgetting, and output gates, each of which has its unique role. The structure of LSTM method is shown in Fig. 4 [29].

❖ The equations for the gates in the LSTM method are as follows;

$$i_t = \sigma(w_i + [h_{t-1}, x_t] + b_i) \quad (8)$$

$$f_t = \sigma(w_f + [h_{t-1}, x_t] + b_f) \quad (9)$$

$$o_t = \sigma(w_o + [h_{t-1}, x_t] + b_o) \quad (10)$$

i_t = Represents the input gate.
f_t = Represents the forget gate.
o_t = Represents the output gate.

σ = Represents the sigmoid function.

w_x = Weight values for the corresponding gate(x) neuron.

h_{t-1} = Represents the output of the previous LSTM block.

x_t = Input value to the current time loop.

b_t = Threshold values for the corresponding gate(x) neuron.

❖ The equations for cell state, candidate cell state and final output in the LSTM model are as follows;

$$\tilde{c}_t = tanh(w_c * [h_{t-1}, x_t] + b_c) \qquad (11)$$

$$c_t = (f_t * c_{t-1}) + (i_t * \tilde{c}_t) \qquad (12)$$

$$h_t = o_t * \tanh(c^t) \qquad (13)$$

c_t = Represents the cell state (memory) in the time loop.

$\tilde{c}_t$ = Represents the candidate cell state (memory) in the time loop.

$*$ = Multiplication process

G. STATISTICAL METRICS

In this phase, two statistical metrics, mean (μ) and standard deviation (σ), were utilized to observe the relationship between different spectral band parameters of substations and non-substation samples. Equations of these metrics are given below, respectively.

$$\mu = 1/n \sum_{i=1}^{n} Xi \qquad (14)$$

$$\sigma = \sqrt{\frac{\sum (X - \mu)^2}{n - 1}} \qquad (15)$$

Here; Xi is the value in data distribution and n is the total number of observations. Additionally, five performance metrics were computed for proposed system by employing the following equations. Furthermore, confusion matrix, ROC curve and Accuracy Graphs were used for demonstrating the success of LSTM method.

$$Sensitivity = \frac{TP}{TP + FN} \qquad (16)$$

$$Specificity = \frac{TN}{TN + FP} \qquad (17)$$

$$Precision = \frac{TP}{TP + FP} \qquad (18)$$

$$F1\text{-Score} = \frac{2TP}{2TP + FP + FN} \qquad (19)$$

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \qquad (20)$$

Here, TP, TN FP, and FN represent true positive, true negative, false positive, and false negative numbers, respectively.

III. RESULTS

In this section, spectral band images of the preprocessed Landsat-8 OLI data are presented as below. Feature vectors (spectral band parameters) were then calculated from pixels

D. OBTAINING B4 SPECTRAL BAND PARAMETERS
In this phase, the image corresponding to the B4 (Red) band of Landsat-8 OLI data is indicated in Fig. 8 and the spectral band parameter values of the different substations and

non-substation objects are tabulated in Table 8 and Table 9, respectively.

As shown in the Table 8, the mean surface reflection values of different substations in the B4 spectral band was computed as 1439.14 and the standard deviation as 360.33.

When the values in Table 9 are examined, the mean surface reflection values of 21 different non-substation objects in the

B4 spectral band was calculated as 1141.47 and the standard deviation as 390.21.

E. OBTAINING B5 SPECTRAL BAND PARAMETERS

In this step, the image corresponding to the B5 (Near Infrared) band of Landsat-8 OLI data is shown in Fig. 9 and the spectral band parameter values of the different substations and non-substation objects are represented in Table 10 and Table 11, respectively.

As illustrated in the Table 10, the mean surface reflection values of different substations in the B5 spectral band was calculated as 3302.11 and the standard deviation as 371.73.

When the values in Table 11 are evaluated, the mean surface reflection values of 21 different non-substation objects in the B5 spectral band was calculated as 2807.39 and the standard deviation as 928.21.

G. OBTAINING B7 SPECTRAL BAND PARAMETERS

In this step, the image corresponding to the B7 (Shortwave Infrared 2) band of Landsat-8 OLI data is illustrated in Fig. 11 and the spectral band parameter values of the different substations and non-substation objects are tabulated in Table 14 and Table 15, respectively.

As presented in the Table 14, the mean surface reflection values of different substations in the B7 spectral band was calculated as 3171.47 and the standard deviation as 405.21.

As seen in the Table 15, the mean surface reflection values of 21 different non-substation objects in the B7 band was computed as 1542.80 and the standard deviation as 558.50.

H. DETERMINING RELATIONSHIPS AMONG SUBSTATIONS

At this stage, a dataset corresponding to the all substations were generated as presented in Table 15 and the correlations of these substations are given in Fig. 12.

I. DETERMINING RELATIONSHIPS AMONG NON-SUBSTATION SAMPLES

At this stage, a dataset corresponding to the all-non-substation samples were constituted as indicated in Table 17 and the correlations of these substations are given in Fig. 13.

J. RECOGNITION OF SUBSTATIONS BY EMPLOYING LOGIT-BOOST ALGORITHM

At this stage, firstly, data sets belonging to two different classes obtained from substations and non-substation samples were combined. Training and test sets were then created with the leave-one-out cross validation approach. Finally, automatic recognition of substations was performed using the Logit-Boosting algorithm and different spectral

band parameters. The performance metrics of the proposed system are shown in Table 18.

K. RECOGNITION OF SUBSTATIONS BY EMPLOYING LSTM

In this section, Table 15 and Table 16 were combined to create a data set. A 'Class' column was created in the data set, containing the value 1 for the values in Table 15 and 0 for the values in Table 16. The success of the system was measured by applying the LSTM model to this data set. Three

FIGURE 14. The test error graph for LSTM method.

FIGURE 15. The test accuracy graph for LSTM method.

figures containing the ROC curve, Accuracy and Loss Graph, Confusion Matrix and Accuracy rate of the model are given in Fig. 14, Fig. 15, Fig. 16 and Fig. 17, respectively.

As shown in Fig. 14, the error level of the system for the LSTM model decreases with the number of epochs. However, the error rate is stable at approximately 140-150 cycles. For this reason, the number of epochs was chosen as 150.

As seen in Fig. 15, the accuracy level of the system for the LSTM model increases with the number of epochs. As in Fig. 14, it can be observed from this figure that the optimum value for the number of epochs is around 140-150.

The ROC curve shown in Fig. 16 includes TPR and FPR values. When the ROC curve is analyzed, it is observed that the system is at an acceptable level.

When Fig. 17 is observed, the model successfully predicted 16 out of 19 values of the test data correctly. Additionally, as can be seen from the confusion matrix, the number of samples for testing is 19. The total number of samples in the data set is 63. This shows that 70% of the data is used for training and 30% for testing. The success rate of the LSTM method is 84.21%.

IV. DISCUSSION

At this stage, statistical analysis of different spectral band parameters corresponding to substation and non-substation samples was discussed and the effects of these band parameters on automatic substation recognition were examined separately.

FIGURE 16. The Roc curve for LSTM method.

FIGURE 17. The confusion matrix and accuracy rate for LSTM method.
When all the tables between Table 2 and Table 15 are considered, it is seen that the mean and standard deviation of the spectral values in each band of all substations are close to each other. This situation is similar for all non-substation samples between Table 2 and Table 15. The reason for this can be explained as similar objects show similar reflection. However, when the mean and standard deviations of the spectral values in each band belonging to substations and non-substations are compared with each other, it can be said that objects belonging to these two classes differ from each other depending on their reflectance values as illustrated in Fig.12 and Fig.13.

Considering the performance metrics in Table 18, it was observed that the highest average accuracy value was computed as 88.9% by utilizing B6 band parameters and Logit-Boosting algorithm. The confusion matrix for this scenario is given in Fig.14. The reason for this may be that the reflection values of different objects can be distinguished more sharply at the Shortwave Infrared 1 wavelength. Because, this wavelength is usually used for discriminating moisture content of soil and vegetation.

As seen in Fig.14, Fig.15, Fig.16 and Fig.17, high success rates were obtained by using the LSTM method in the proposed approach. Due to the low number of data, deep learning systems can sometimes give low success levels. In such cases, the model layers should be well tuned and overlearning should be avoided. The situation is different in data sets with high amount of data. Overlearning rarely occurs. High accuracy values can be achieved with fewer cycles. Although the data in the data set obtained with the existing substations in the studied area is limited, very successful results have been obtained.

Considering the studies in the literature, there is no similar study on recognizing substations with the help of passive satellite image, machine learning approaches and LSTM method. For this reason, while creating the comparison table below, studies on the detection of different objects using machine learning techniques, LSTM method and passive satellite systems are included as seen in Table 19.

V. CONCLUSION

The use of geographical information systems together with remote sensing techniques is extremely important in the determination of spectral band parameters of various objects. In this study, different spectral band parameters of the Landsat-8 OLI images have been determined in order to determine relationships among the 42 substations and 21 non-substation objects.

The proposed work consists of several stages. In the first stage, the terrains on the Sason district of Batman province were chosen as the study area. In the second stage, the positions of the 42 substations and 21 non-substation objects have been registered thanks to GPS equipment and the GPS data have been then imported to the Landsat-8 OLI images In the next stage, image analysis was performed to calculate spectral band parameters from Landsat-8 OLI data. In addition, utilizing the statistical metrics of the obtained spectral band parameters, the relations among the substations and non-substation objects were established.

Therefore, the feature extraction step, which is essential for the automatic identification of substations, has been accomplished to form datasets. In the last stage, automatic recognition of substations has been performed with high average accuracy by employing obtained dataset, Logit-Boosting algorithm and LSTM method.

When compared with similar studies in the literature, this study achieved high success rates and addresses a previously unexplored subject. The models employed are some of the most popular recently, and it was observed that the detection of substations using Landsat-8 satellite can be done with great accuracy through the LSTM model and Logit-Boost algorithm. Of course, it is worth pointing out that these success rates may increase further by using larger datasets.

As a continuation of this work in the future, it is planned to detect the substations by different spectral band parameters obtained from various satellite data with the aid of different deep learning and machine learning methods With this proposed study, it is thought to prevent illegal electricity consumption.

DECLARATIONS CONFLICTS OF INTEREST

The authors declared that there is no conflict of interest regarding this work.

ENES BAKIŞ received the B.S. degree in electrical and electronics engineering from Batman University, Batman, Turkey, in 2021, and the M.S. degree in electrical and electronics engineering from Batman University, where he is currently pursuing the Ph.D. degree in electrical and electronics engineering. He currently works as a Research Assistant at Piri Reis University, Istanbul. His research interests include digital image processing, machine learning, deep learning, and remote sensing applications.

EMRULLAH ACAR received the B.S. degree in electrical and electronics engineering from Çukurova University, Adana, Turkey, in 2009, the first M.S. degree in biomedical engineering from Istanbul Technical University, Istanbul, Turkey, in 2010, and the second M.S. and Ph.D. degrees in electrical and electronics engineering from Dicle University, Diyarbakır, Turkey, in 2012 and 2017, respectively. He is currently an Associate Professor of electrical and electronics engineering with Batman University and also the Head of the Electronics Division. He received awards and honors, include the Scientific and Technological Research Council of Turkey (TUBITAK) Grant; Erasmus Mobility Grant, Sweden; and Erasmus Internship Grant, Germany. His research interests include digital image processing, machine learning, and remote sensing applications.

MUSA YILMAZ (Senior Member, IEEE) received the M.Sc. and Ph.D. degrees in electrical education from Marmara University, Istanbul, Turkey, in 2004 and 2013, respectively. He currently holds the position of an Assistant Professor with the Electrical and Electronics Engineering Department and the Energy Engineering Department, Batman University. From 2015 to 2016, he joined the Smart Grid Research Center (SMERC), The University of California, Los Angeles (UCLA), as a Visiting Scholar. He has conducted extensive research in the field of smart grids and solar energy. Along with Biosys LLC, he is an inventor of a ventilator class named "Biyovent." He has made significant contributions to academia and publishing. Additionally, he is a Co-Founder of INESEG, a publishing organization. He has authored over 50 research articles, several book chapters, and frequently delivers invited keynote lectures at international conferences. He has also led his research team as the principal investigator in several European projects. His primary research interests revolve around smart grid technologies and renewable energy. He served as the Editor-in-Chief for the *Balkan Journal of Electrical and Computer Engineering* (BAJECE) and the *European Journal of Technique* (EJT).
