

A Wireless Charging System Applying Phase-Shift and Amplitude Control to Maximize Efficiency and Extractable Power

Andreas Berger, *Student Member, IEEE*, Matteo Agostinelli, Sanna Vesti, Jesús A. Oliver, *Member, IEEE*, José A. Cobos, *Senior Member, IEEE*, and Mario Huemer, *Senior Member, IEEE*

Abstract—Wireless power transfer (WPT) is an emerging technology with an increasing number of potential applications to transfer power from a transmitter to a mobile receiver over a relatively large air gap. However, its widespread application is hampered due to the relatively low efficiency of current Wireless power transfer (WPT) systems. This study presents a concept to maximize the efficiency as well as to increase the amount of extractable power of a WPT system operating in nonresonant operation. The proposed method is based on actively modifying the equivalent secondary-side load impedance by controlling the phase-shift of the active rectifier and its output voltage level. The presented hardware prototype represents a complete wireless charging system, including a dc–dc converter which is used to charge a battery at the output of the system. Experimental results are shown for the proposed concept in comparison to a conventional synchronous rectification approach. The presented optimization method clearly outperforms state-of-the-art solutions in terms of efficiency and extractable power.

Index Terms—Dc–dc power converters, impedance matching, inductive power transmission, phase-shift control, reactive power control, rectifiers, wireless charging.

I. INTRODUCTION

WIRELESS power transfer (WPT) is used in various application fields ranging from a few milliwatts in biomedical applications [1]–[3] up to several kilowatts of output power in automotive applications [4]–[6]. Currently, WPT systems intended to wirelessly charge consumer electronic devices, such as mobile phones or tablet computers, are studied extensively [7]–[10]. Various aspects of these systems are defined by several standards which are either based on nonresonant or inductive power transfer (IPT), like the Qi standard [11] or on resonant power transfer (RPT), like the Rezence standard [12]. In order to ensure interoperability of different transmitter and receiver

devices, these standards define parameters such as the voltage range, the basic circuit structure, and the operating frequency of the system. The main drawbacks of currently available WPT systems for consumer applications are, amongst others, the relatively low overall efficiency and the limited power transfer capability. This results in long charging times which hampers the widespread application of the WPT technology.

To overcome these problems, various improvements have been suggested in the literature. Design and optimization methodologies for increasing the efficiency or the maximum transferable power of a WPT link have been proposed in [13]–[16], assuming that the system parameters are freely selectable. However, these optimization strategies are not applicable to commercial charging applications, where the system parameters are defined by a standard.

On the other hand, various optimization methods which are in accordance with current standards are reported. In [17], different control strategies for the transmitter of a WPT system are compared regarding their impact on the output power and the efficiency. Furthermore, in [18], a control scheme for a synchronous rectifier on the secondary side is proposed to improve the efficiency in comparison to a passive and semiactive rectifier solution.

Although WPT has been extensively studied in recent years, less attention has been paid to the optimization of an entire wireless charging system, starting from a dc input source to charging a battery at the output. In [19], a Qi compliant wireless charging system has been presented but only commercial available components have been used and no advanced optimization techniques have been applied to increase the system efficiency and the extractable output power. In [9], a dual mode receiver architecture is presented which is capable of operating according to the Qi standard (110–205 kHz) and the Rezence standard (6.78 MHz). Experimental results, from the input of the rectifier to the battery at the output, show a higher efficiency for the nonresonant operating mode mainly due to lower switching losses.

In a wireless charging system the efficiency and the amount of power transferred to the output are influenced by the source (transmitter) and load (receiver) impedances. In [20], the load impedance is assumed to be purely resistive and, therefore, efficiency improvements are reported by only adjusting the resistive part of the load impedance. However, this approach does not yield optimal efficiency for the whole operating range, since only the resistive part of the load impedance is altered and the

reactive part is not considered at all. The maximum amount of power can be transferred by modifying the load impedance to match the complex conjugate of the source impedance [21]. An impedance adjustment unit is applied in [22] to cancel the reactive part of the impedance and thereafter to alter the resistive part in order to yield maximum power transfer. Yet, this technique uses a network of passive components to adjust the impedance, and it targets only to achieve the maximum extractable output power while the system efficiency is not optimized. Additional improvements to the efficiency of a WPT system are obtained by actively modifying the reactive part of the load impedance. In [23], a phase-shift control approach, instead of a conventional controlling method, is applied to the active rectifier on the secondary side of an RPT system. This technique is used to achieve efficiency improvements by modifying the secondary-side resonance frequency, but on the other hand it also impacts the equivalent load impedance. Since the phase-shift is the only control parameter, the resistive as well as the reactive part of the equivalent load impedance are concurrently altered. Hence, these two parameters cannot be controlled separately and the point of maximum efficiency is not reached in general. Furthermore, it might be highlighted that [23] solely investigates an RPT system with a resistive load at the output of the rectifier.

In this study, an advanced optimization strategy for an entire wireless charging system, including an active rectifier and a dc–dc converter charging a battery, is investigated in detail. The presented approach assumes nonresonant operation (IPT) and is based on the Qi standard specifications. When applied to an RPT system operating exactly at resonance frequency, the reactive part of the system is inherently compensated, and hence the proposed approach shows the same behavior as a synchronous rectifier. However, any deviation from the resonance frequency, caused, e.g., by parameter variations of the passive components, enables a performance increase of the proposed concept over a synchronous rectification approach. An improved control strategy to actively adjust the resistive as well as the reactive part of the equivalent load impedance is introduced in order to optimize the system performance. This approach, applicable to any IPT system, is used to further improve the system efficiency and to extract more power. The presented methodology is based on controlling both the phase-shift of the active rectifier and its output voltage level. This study is an extension to the concept we proposed in [24], where only a simplified system has been investigated and a voltage source at the output of the rectifier is used to set a desired voltage level. In contrast, this paper investigates a complete wireless charging system, including a dc–dc converter to regulate the rectified voltage and a battery as load of the system. The acquired simulations and experimental results show that the proposed concept is capable of achieving significant performance improvements in terms of efficiency and extractable power when compared to prior solutions.

The remainder of this paper is organized as follows: In Section II, the theoretical background of the presented methodology is derived and thereafter in Section III the proposed concept is discussed in detail. In Section IV, the applied optimization strategy is introduced and in Section V the architecture of the

investigated wireless charging system as well as experimental results acquired from the WPT prototype are presented. Finally, in Section VI the major findings of this study are summarized and concluding remarks are given.

II. THEORETICAL ANALYSIS

In this section, the methodology for modeling the behavior of the WPT system is introduced and the theoretical conditions for calculating the maximum efficiency and the maximum power transfer are provided. This study focuses on a circuit-based model, but it is worth noting that there exist different other possibilities to model WPT systems [13], [25], [26]. A block diagram of the examined system is shown in Fig. 1.

A. System Modeling

The first harmonic approximation is used to analyze the WPT system shown in Fig. 1. This method only considers the fundamental component of the input voltage [15], [25], [27] and replaces the active rectifier as well as the dc–dc converter by an equivalent first harmonic impedance $Z_L = R_L + jX_L$. The applied simplification is sufficiently accurate for high quality factor resonant circuits that operate near resonance frequency. This study focuses on the steady-state analysis of a series-series resonant WPT system as shown in Fig. 2, but the proposed concept is applicable to every topology.

The sinusoidal voltage source V_{in} is an equivalent root mean square (RMS) input voltage which is driving the primary side resonance circuit. The series resistances R_p and R_s represent the overall parasitic resistances of the primary and the secondary side resonance circuit. The series capacitors C_p and C_s are required to tune the resonance frequency of the primary and the secondary side, while the mutual inductance M depends on the coupling factor $k = M\sqrt{L_p L_s}$, which is influenced by the geometry, the distance, and the alignment of the inductors

Fig. 3. Circuit model of the WPT system using two equivalent sources to model the coupling between the inductors L_p and L_s .

L_p and L_s . The open-circuit impedances of the primary and secondary side resonance circuits are defined as

$$Z_p = R_p + jX_p = R_p + j \left(\omega L_p - \frac{1}{\omega C_p} \right) \quad (1)$$

$$Z_s = R_s + jX_s = R_s + j \left(\omega L_s - \frac{1}{\omega C_s} \right). \quad (2)$$

The equivalent load impedance of the WPT system can be modeled as a complex impedance $Z_L = R_L + jX_L$, which represents the overall impedance seen by the secondary side resonance circuit, including the rectifier, the dc-dc converter and the battery at the output of the system. The impedances Z_{in} and Z_o , as shown in Fig. 2, are the equivalent impedances seen by the source and by the output, respectively. They can be expressed as

$$Z_{in} = Z_p + \frac{X_m^2}{Z_s + Z_L} \quad (3)$$

$$Z_o = Z_s + \frac{X_m^2}{Z_p} \quad (4)$$

where $X_m = \omega M$ represents the mutual impedance of the coupled inductors. To further simplify the ac circuit model in Fig. 2, the coupled inductors L_p and L_s can be modeled as equivalent current controlled voltage sources at the primary and the secondary side as shown in Fig. 3.

The induced voltage at the secondary side is influenced by the primary side current I_p and can be denoted by $jX_m I_p$. On the other hand, the current at the secondary side I_L also causes an induced voltage at the primary side inductor which is determined by $-jX_m I_L$. Furthermore, V_{in} represents the input and V_L the output voltage, and I_p the input and I_L the output current of the system. The impedances Z_p and Z_s are defined according to (1) and (2).

B. Efficiency and Extractable Power

In order to analyze the system performance, the input and output power of the WPT system are derived as a function of the resistive part R_L and the reactive part X_L of the equivalent load impedance. The following relations for the mean input power P_{in} , respectively the mean output power P_{out} , are based

TABLE I
SUMMARY OF THE POSSIBILITIES TO OPTIMIZE THE EQUIVALENT LOAD IMPEDANCE OF A WPT SYSTEM

Load Impedance	Optimization Concept
$Z_L = R_L + j0$	synchronous rectification (purely resistive behavior)
$Z_L = R_L - jX_s$	single point optimization (cancellation of reactive part)
$Z_L = R_o - jX_o = Z_o^*$	maximum power transfer approach (conjugate matching)
$Z_L = R_L(\varphi) + jX_L(\varphi)$	pure phase-shift (no independent adjustment of R_L and X_L)
$Z_L = R_L(\varphi, V_r) - jX_L(\varphi, V_r)$	proposed approach (separate adjustment of R_L and X_L)

on the equivalent model in Fig. 3 and are given as

$$P_{in}(R_L, X_L) = \frac{V_{in}^2 [R_p + \text{Re}\{Z_r\}]}{[R_p + \text{Re}\{Z_r\}]^2 + [X_p + \text{Im}\{Z_r\}]^2} \quad (5)$$

$$P_{out}(R_L, X_L) = \frac{V_{in}^2 X_m^2 R_L}{\text{den}} \quad (6)$$

where

$$\begin{aligned} \text{den} = & [R_p (R_s + R_L) - X_p (X_s + X_L) + X_m^2]^2 \\ & + [X_p (R_s + R_L) + R_p (X_s + X_L)]^2 \end{aligned}$$

and V_{in} denotes the RMS value of the input voltage of the system. The impedance Z_r represents the reflected impedance from the secondary to the primary side which can be derived as

$$Z_r = \frac{X_m^2}{Z_s + Z_L}. \quad (7)$$

It is well known from the literature that the maximum output power can be achieved by a conjugate matching of the equivalent load and output impedance of the system ($Z_L = Z_o^*$) [14], [21].

With the relations (5) and (6) for the input and output power, the system efficiency as a function of the load impedance can be expressed as

$$\begin{aligned} \eta(R_L, X_L) &= \frac{X_m^2 R_L}{R_p \left[(R_s + R_L)^2 + (X_s + X_L)^2 \right] + X_m^2 (R_s + R_L)}. \end{aligned} \quad (8)$$

In case only the efficiency is considered, (8) can be maximized by canceling the reactive part ($X_L = -X_s$) and by solely optimizing the real part R_L of the equivalent load. The optimal load resistance can then be derived by setting the derivative of (8) to zero which yields [25]

$$R_{L,opt} = \sqrt{R_s^2 + \frac{R_s}{R_p} X_m^2}. \quad (9)$$

This approach is referred to as single-point efficiency optimization in the following, since it maximizes the efficiency only for a

TABLE II
SUMMARY OF THE MAIN SYSTEM PARAMETERS

	Parameter	Symbol	Value
	input voltage	V_s	19 V
general parameters	coupling factor	k	0.6/0.3
	resonance frequency	f_{res}	100 kHz

	series resistance	R_{Bat}	70 m Ω

single value of the output power which can be far from the maximum output power of the system. If the output power is varied by altering the load resistance R_L , the efficiency decreases and the system does not operate at the optimum efficiency for this particular value of the output power. It is worth noting that the conditions ($R_L = R_{L,opt}$, $X_L = -X_s$) for maximum efficiency, and ($Z_L = Z_o^*$) for maximum power transfer are in general not fulfilled at the same time. To overcome these drawbacks and to achieve optimum efficiency for every possible value of output power, an optimization method is required to adjust both the resistive and the reactive part of the equivalent load impedance.

III. PROPOSED CONCEPT

In this section synchronous rectification is briefly reviewed and, thereafter, the proposed concept for controlling the equivalent load impedance to optimize the efficiency and to increase the power transfer capability is discussed in detail. Simulation results are shown for a WPT system based on the Qi low-power specifications, operating at a frequency of 140 kHz with a resonance frequency of 100 kHz. The values used for simulation are based on the parameters of the experimental setup which are summarized in Table II in Section V.

A. Synchronous Rectification

Synchronous rectification is a commonly used technique to control an active rectifier, where the switches of the full bridge are driven according to the zero crossings of the rectifier input current I_L . Thus, the controller forces the current I_L and the voltage V_L at the input of the rectifier to be in phase ($\varphi = 0$), which results in a purely resistive behavior of the rectifier without compensation of the reactive part ($Z_L = R_L + j0$). Fig. 4 schematically illustrates the key waveforms of the synchronous rectification approach. To obtain the maximum efficiency for every point of the output power P_{out} the rectified voltage V_r is adjusted by controlling the duty cycle D of the dc-dc converter.

B. Proposed Concept

Recent research [23] has shown the possibility to improve the performance of a WPT system by introducing a phase-shift

Fig. 4. Rectifier input voltage V_L and current I_L for synchronous rectification ($\varphi = 0$).

between the primary and secondary side voltages. However, this method does not allow to separately control the resistive and reactive part of the equivalent load impedance, whereas in the proposed concept the overall impedance is controlled. By defining the phase-shift φ as the angle between the first harmonic of the input current I_L and the voltage V_L of the active rectifier we derived an analytical expression for the equivalent input impedance of the active rectifier [24]

$$\begin{aligned} Z_L(\varphi, V_r) &= R_L + jX_L = \frac{V_L^{(1)}}{I_L^{(1)}} = \frac{4}{\pi} \frac{V_r}{I_L^{(1)}} e^{-j\varphi} \\ &= \frac{4}{\pi} \frac{V_r}{I_L^{(1)}} (\cos(\varphi) - j \sin(\varphi)) \end{aligned} \quad (10)$$

where $V_L^{(1)}$ and $I_L^{(1)}$ represent the amplitude of the first harmonic of the voltage V_L and the current I_L . By analyzing (10), it can be observed that a variation in the phase results in a change of the resistive as well as the reactive part of the equivalent load impedance. This behavior limits the optimization possibilities in case only the phase is actively controlled. On the other hand (10) shows the possibility to further improve the system by modifying a second parameter, the rectified voltage V_r . This parameter can be controlled by either altering the duty cycle δ of the active rectifier or by adjusting the voltage regulator at the output of the system. Fig. 5(a) schematically illustrates the phase-shift concept using the duty cycle D of the dc-dc converter to adjust the rectified voltage V_r , and Fig. 5(b) shows the phase-shift and duty cycle δ control method for the active rectifier. It is worth noting that these waveforms are schematic illustrations and do not yield the same equivalent resistance R_L for the shown case.

By correctly adjusting D or δ the same value of rectified voltage V_r and hence the same equivalent resistance R_L can be achieved. The fundamental component of the rectifier input voltage V_L for the case of the duty cycle D control [see Fig. 5(a)] and the δ control [see Fig. 5(b)] can be denoted by

$$V_L^{(1)}(\varphi, D) = \frac{4}{\pi} V_r e^{-j\varphi} = \frac{4}{\pi} \frac{V_\ell}{D} e^{-j\varphi} \quad (11)$$

$$V_L^{(1)}(\varphi, \delta) = \frac{4}{\pi} V_r \sin(\delta/2) e^{-j\varphi} \quad (12)$$

where $0 \leq D \leq 1$ and $0 \leq \delta \leq \pi$. Consequently, both of the presented control approaches can be used to regulate the rectified

Fig. 5. Schematic illustration of the key waveforms of the proposed method. (a) Voltage V_L and current I_L at the input of the rectifier utilizing the duty cycle D of the dc-dc converter to control the amplitude of the rectified voltage V_r . (b) Voltage V_L and current I_L at the input of the rectifier using the duty cycle δ of the active rectifier to adjust the rectified voltage V_r .

voltage V_r , but in this study the impact of the duty cycle D of the employed dc-dc converter is investigated in detail. The relation between the voltage regulator input (V_r) and output voltage (V_o) affects the resistive part of the equivalent load impedance. Hence, a change in the rectified voltage can be used to modify the equivalent load resistance R_L .

IV. OPTIMIZATION STRATEGY

In this section, two methods to obtain the maximum efficiency for a desired amount of output power are presented. The first approach is based on the numerical optimization of the efficiency for a given output power using the resistive and reactive part of the equivalent load impedance. Since it is not straightforward to obtain the values of R_L and X_L during steady state, a second optimization method is introduced, where the rectifier input current I_L is optimized as a function of the phase-shift φ and the rectified voltage V_r . These two measurable parameters can be used to achieve the maximum efficiency of the system for every value of the output power. It is worth noting that both presented optimization methods yield the same performance. Additionally, simulation results of the proposed concept are presented and compared to other state-of-the-art optimization approaches. The different possibilities discussed in this paper to optimize the load impedance are summarized in Table I.

A. Optimization of the Resistive and Reactive Part

By controlling the resistive as well as the reactive part of the equivalent load impedance it is possible to optimize the

system efficiency for a desired value of the output power. In order to calculate the optimum load impedance a constrained optimization process for every desired value of the output power is used. Mathematically, this constrained optimization can be formulated as

$$Z_{L,\text{opt}}(P_{\text{out}}) = \arg \max_{R_L, X_L} (\eta(R_L, X_L) |_{P_{\text{out}}}) \quad (13)$$

which can be numerically solved with an appropriate software tool, e.g., with MATLAB. Fig. 6 presents the results of the constrained optimization process in (13) at a constant operating frequency of 140 kHz for a relatively high coupling factor $k = 0.6$ and a low coupling factor of $k = 0.3$. The plots compare the impedance behavior as well as the achieved efficiency of the maximum power approach (conjugate matching of load and output impedances $Z_L = Z_o^*$ and optimizing R_L), the synchronous rectification approach (purely resistive R_L) and the proposed approach (optimizing both, the resistive and the reactive part). Additionally, the point of maximum efficiency, obtained with the single-point optimization approach ($R_L = R_{L,\text{opt}}, X_L = -X_s$), is marked in the plots. Fig. 6(a) and (b) illustrates the behavior of the resistive and the reactive part, respectively, over the output power for a tightly coupled system ($k = 0.6$). The efficiency of the different approaches in dependence on the output power is shown in Fig. 6(c). Fig. 6(d)–(f) presents the results for the same system with a lower coupling factor $k = 0.3$.

The variation of the phase-shift adds an additional degree of freedom for the proposed control method, thus achieving an increased overall efficiency and a higher power transfer capability when compared to the conventional optimization approaches. For tight coupling ($k = 0.6$), the synchronous rectification achieves a lower system efficiency in the low power region as well as at the end of the medium power range when compared to the proposed method. Additionally, the maximum amount of extracted power is limited when using synchronous rectification while the presented method is able to obtain the maximum possible output power. When utilizing the maximum power approach, the results show a considerably lower efficiency over the whole operating range compared to the optimized concept. If the output power is increased, the optimal values of R_L and X_L are approaching the values of the maximum power method. At the point of maximum power both approaches yield the same values for the optimal resistive and reactive part of the system. Canceling the reactive part (single-point optimization) achieves the maximum efficiency only for a single point of output power. At this point the obtained values for R_L and X_L are the same as for the proposed concept. On the other hand, for different values of output power the efficiency is significantly reduced when compared to the proposed method.

For a system with a lower coupling factor $k = 0.3$ the benefit of the proposed concept in terms of efficiency gain and higher power transfer capability significantly increases when compared to a synchronous rectification approach, as shown in Fig. 6(d)–(f). The simulation results clearly highlight the achievable advantage in performance of the proposed concept by increasing

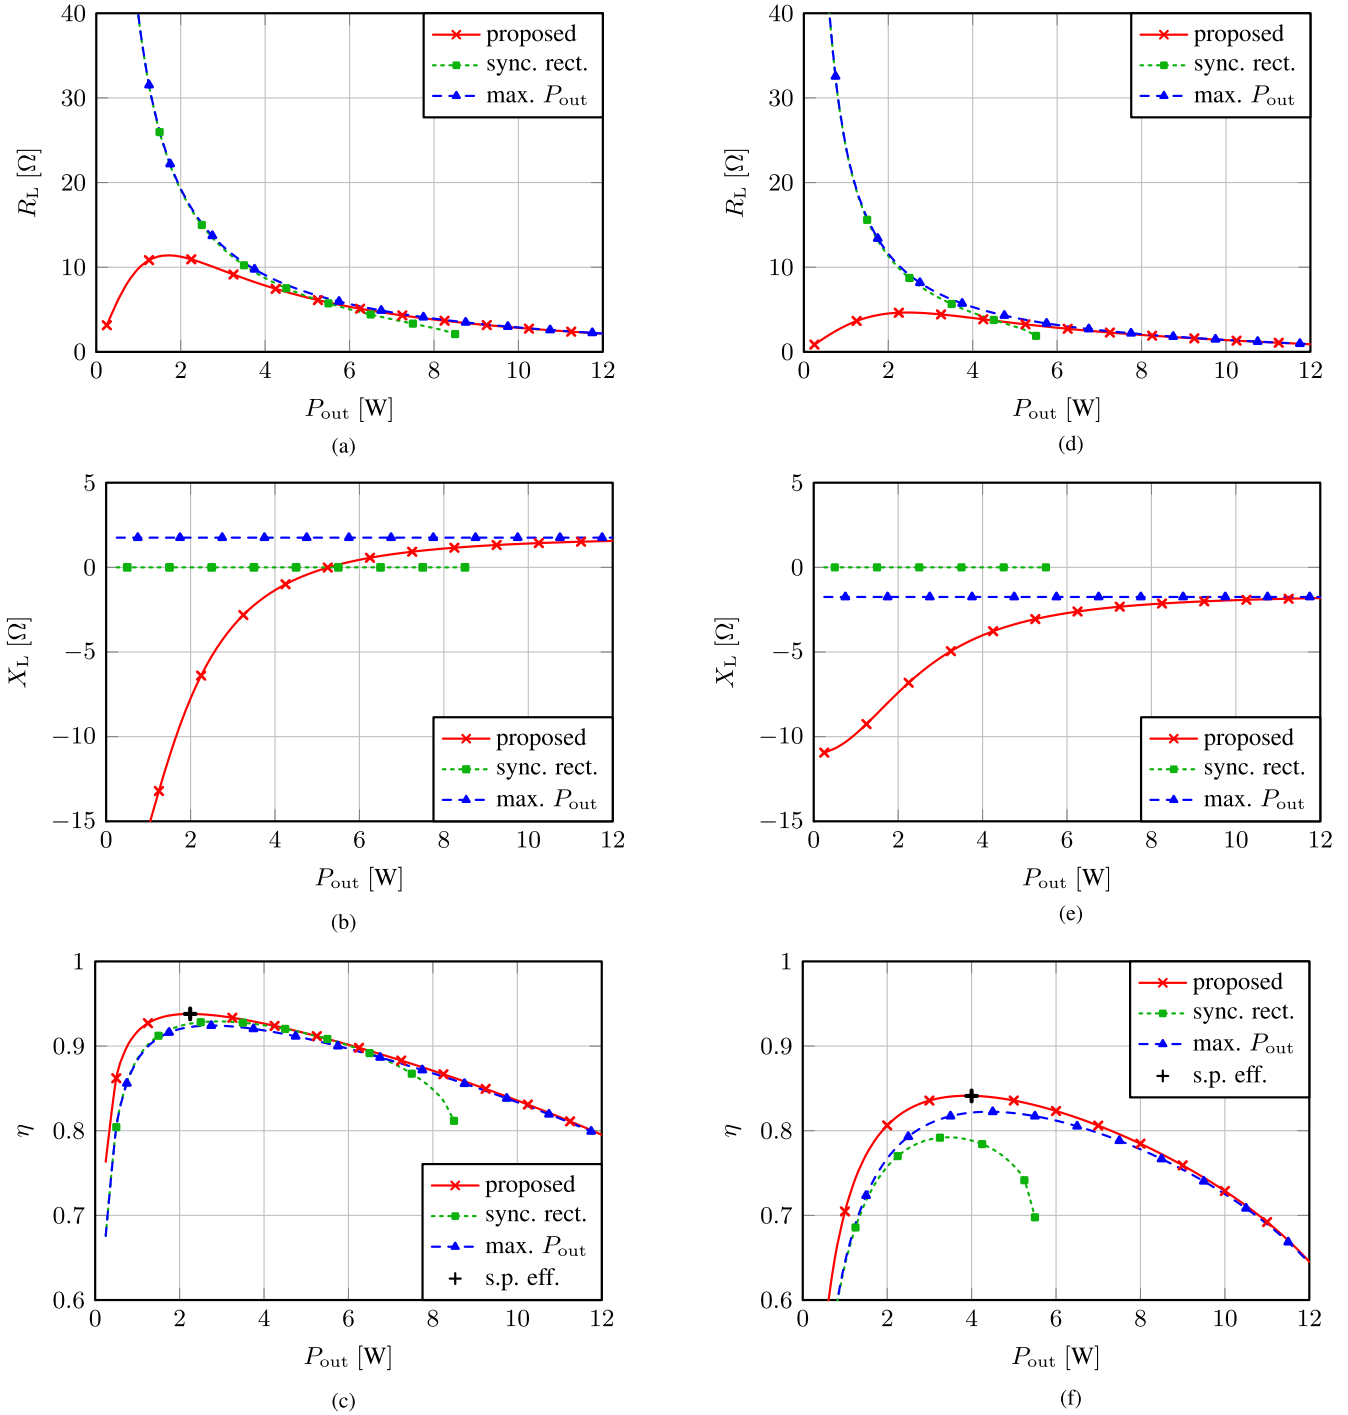

Fig. 6. Impedance behavior and efficiency of the proposed concept compared to the maximum power approach and a synchronous rectifier. (a) Resistive part R_L over output power P_{out} for $k = 0.6$. (b) Reactive part X_L over output power P_{out} for $k = 0.6$. (c) Efficiency η over output power P_{out} for $k = 0.6$. (d) Resistive part R_L over output power P_{out} for $k = 0.3$. (e) Reactive part X_L over output power P_{out} for $k = 0.3$. (f) Efficiency η over output power P_{out} for $k = 0.3$.

the efficiency for the same amount of output power and pushing the power transfer capability of the system.

B. Optimization of the Phase-Shift and Rectified Voltage

This section introduces a second possibility to solve the constrained optimization problem in (13) based on measurable

system parameters. In this approach, the optimal rectifier input current $I_{L,opt}$ and the optimal load impedance $Z_{L,opt}$ in dependence on the phase-shift φ and the rectified voltage V_r are derived to obtain the highest possible system efficiency for every value of the desired output power. Additionally, simulation results are presented and compared to experimental results. To obtain the optimal system parameters, the system in Fig. 2

is represented as a two-port network which can be denoted in matrix form as

$$\begin{pmatrix} I_p \\ V_L \end{pmatrix} = \begin{pmatrix} Y_{11} & A_{12} \\ A_{21} & -Z_{22} \end{pmatrix} \begin{pmatrix} V_{in} \\ I_L \end{pmatrix} \quad (14)$$

where the gain $A_{12} = A_{21}$ represents the ratio of the input current I_p to the output current I_L if the primary side is shorted, respectively the ratio of the secondary side voltage V_L to the primary side voltage V_{in} in case the secondary side is open. A_{12} can be calculated by

$$A_{12} = \frac{jX_m}{R_p + j(X_p + X_m)}. \quad (15)$$

The impedance Z_{22} represents the output impedance of the wireless link in case the primary side is shorted, it can be derived as

$$Z_{22} = Z_s + \frac{jX_m Z_p}{R_p + j(X_p + X_m)}. \quad (16)$$

In order to calculate the optimum value of the impedance for every value of the output power an analytic solution for the constrained optimization process in (13) has been derived based on Lagrangian optimization methods. Since the efficiency is defined as the ratio between the input and output power, and P_{out} is a fixed value during the optimization process, the efficiency can be maximized by minimizing the input power P_{in} . Hence, the objective and the constraint for the Lagrangian optimization can be denoted by

$$P_{in} = \text{Re} \{ V_{in}^* I_p \} = V_{in} \text{Re} \{ I_p \} \quad (17)$$

$$P_{out} = \text{Re} \{ V_L^* I_L \} = \text{constant} \quad (18)$$

respectively, where the phase of the input voltage V_{in} is referenced as 0° during the calculations, and hence V_{in} is purely real. For the proposed system a constant input voltage V_{in} , a constant coupling factor k and a constant operating frequency are assumed and hence the input power in (17) can be optimized by minimizing the primary side current I_p . After solving the constrained optimization problem in (17) and (18), the optimized output current $I_{L,opt}(P_{out}, V_{in}) = I_{L,opt}^R(P_{out}, V_{in}) + jI_{L,opt}^I(P_{out}, V_{in})$ for a given amount of output power and a constant input voltage can be calculated as

$$I_{L,opt}^R(P_{out}, V_{in}) = V_{in} \frac{\text{Re} \{ A_{12} \} \left[-\sqrt{1 - \frac{4P_{out} \text{Re} \{ Z_{22} \}}{V_{in}^2 |A_{12}|^2}} + 1 \right]}{2\text{Re} \{ Z_{22} \}} \quad (19)$$

$$I_{L,opt}^I(P_{out}, V_{in}) = V_{in} \frac{\text{Im} \{ A_{12} \} \left[1 + \sqrt{1 - \frac{4P_{out} \text{Re} \{ Z_{22} \}}{V_{in}^2 |A_{12}|^2}} \right]}{2\text{Re} \{ Z_{22} \}} \quad (20)$$

where $I_{L,opt}^R$ denotes the real and $I_{L,opt}^I$ the imaginary part of the current $I_{L,opt}$. With (19) and (20) the optimum equivalent load impedance to achieve the maximum efficiency for a given amount of output power can be derived as

$$Z_{L,opt}(P_{out}, V_{in}) = \frac{A_{12} V_{in}}{I_{L,opt}(P_{out}, V_{in})} - Z_{22}. \quad (21)$$

(a)

(b)

Fig. 7. Comparison of the simulation results with the measured values of the experimental setup. (a) Rectified voltage V_r as a function of the output power P_{out} . (b) Duty cycle D of the dc-dc converter over output power P_{out} .

In order to calculate the optimal values of the rectified voltage V_r and the phase-shift φ , (10) has to be solved at the point of optimal impedance $Z_L = Z_{L,opt}$, which gives

$$V_r(Z_{L,opt}) = \frac{\pi\sqrt{2}}{4} |(A_{21} V_{in} - Z_{22} I_{L,opt})| \quad (22)$$

$$\varphi(Z_{L,opt}) = -\arg \left[\frac{\pi\sqrt{2}}{4} (A_{21} V_{in} - Z_{22} I_{L,opt}) \right]. \quad (23)$$

With the rectified voltage in (22), and if the dc output voltage V_ℓ at the battery is assumed to be constant, the optimal duty cycle D of an idealized dc-dc converter can be derived as

$$D(Z_{L,opt}) = \frac{V_\ell}{|V_r(Z_{L,opt})|}. \quad (24)$$

The values of the rectified voltage V_r and the duty cycle D of the dc-dc converter are measurable on the prototyping system during steady-state operation. Hence, the point of maximum efficiency for every value of output power can be obtained on hardware and compared to the theoretical results. Fig. 7(a) shows a comparison of the simulation results of V_r obtained from (22) to the measurement results of the developed prototyping system. Fig. 7(b) compares the simulations according to (24) and the

experimental results of the duty cycle D as a function of the output power P_{out} .

Fig. 7(a) shows that the value of the rectified voltage V_r is decreasing till an output power of about 8 W. At that point the maximum of the optimal phase-shift is reached and the rectified voltage begins to rise again. Hence, there is a large range of output power values where the rectified voltage only changes marginally, which can be exploited in an optimal control concept. The acquired experimental results are in good agreement with the simulations, especially in the low to medium power range up to 8 W.

In Fig. 7(b) the duty cycle D increases up to an output power of around 8 W. Then it starts to decrease since the maximum value of the optimal phase-shift is reached. Simulations and experimental results again match quite well, a major reason for the deviations is the fact that an ideal model of a dc–dc converter is assumed and the converter efficiency is not considered in the derived analytical equations for simplicity.

V. EXPERIMENTAL RESULTS

This section provides detailed information about the experimental setup and the system parameters used for the measurements. Furthermore, the acquired measurement results using the proposed concept are compared to a synchronous rectifier solution.

A. Prototyping Setup

To verify the results obtained by the simulations an IPT prototyping system has been designed based on the Qi standard specifications [11]. The system is intended to operate at frequencies between 110 and 205 kHz with a resonance frequency of $f_{\text{res}} = 100$ kHz. For the following measurements, a dc supply voltage of $V_s = 19$ V and a constant operating frequency of $f_{\text{op}} = 140$ kHz is used. The primary side inductor L_p [28] with an outer diameter of 43 mm is driven by an inverter stage, switching at the operating frequency of the system. The secondary side inductor L_s [29] with an outer diameter of 28 mm is placed at a distance of 3 mm from the primary side, resulting in a measured coupling factor of $k = 0.6$. For the low coupling factor measurements the distance between the inductors has been increased to 10 mm, yielding a measured coupling factor of $k = 0.3$. At the secondary side an active rectifier is utilized to rectify the induced ac voltage, and an output capacitor $C_r = 22 \mu\text{F}$ is used for stabilizing the rectified voltage. A dc–dc converter, designed for constant-current constant-voltage charging operation, is connected at the output of the rectifier to charge the battery. At the output of the system, a special battery emulation equipment [30] has been attached, and its parameters have been adjusted to simulate the typical behavior of a lithium-ion battery [31]. The digital control of the whole wireless charging system has been implemented on an external field programmable gate array (FPGA) board [32]. A schematic overview of the entire prototyping system is shown in Fig. 8, and a summary of the main system parameters is given in Table II.

To validate the proposed concept, the controller of the primary and secondary side is implemented on an FPGA which controls the switches of the inverter stage ($Q_1 - Q_2$) as well as

the active rectifier ($S_1 - S_4$) and the dc–dc converter ($T_1 - T_2$). In the current prototyping system, which is intended to demonstrate the advantages of the proposed concept, the phase-shift φ between I_L and V_L is realized by inserting a time delay between the primary and secondary side control signals. To achieve this, a communication link between the primary and secondary side controller has been assumed. The current controller implementation operates in open loop. The calculated optimal values are used as initial conditions, and then the control parameters φ and D are iteratively adjusted to compensate for parameter variations and to achieve optimal system performance. The higher the uncertainty of the system parameters, the less accurate are the calculated results of the optimum operation conditions.

B. Experimental Results

In order to validate the proposed concept, the values of the phase-shift φ and the rectified voltage V_r , which is controlled by the duty cycle D of the dc–dc converter, have been adjusted during the measurements to achieve maximum efficiency for each value of the output power. For the synchronous rectification, a zero-crossing detection of the rectifier input current I_L is implemented and the full bridge ($S_1 - S_4$) is driven accordingly. The duty cycle D of the dc–dc converter is used to control the equivalent load resistance and hence the amount of power at the output of the system.

When utilizing the proposed optimization method for a coupling factor $k = 0.6$, the measured point of maximum efficiency $\eta = 77.3\%$ is reached at an output power of $P_{\text{out}} = 3$ W with a phase-shift $\varphi = 20^\circ$ and a duty cycle $D = 68\%$. Fig. 9(a) shows a measurement of the waveforms of the rectifier input voltage V_L and the input current I_L employing these conditions. Fig. 9(b) shows the same waveforms for the synchronous rectification approach using comparable conditions as in Fig. 9(a) (duty cycle $D = 66\%$, output power $P_{\text{out}} = 2.8$ W and efficiency $\eta = 75.9\%$).

As shown in Fig. 9, the proposed control method introduces a phase-shift between the input current I_L and the input voltage V_L of the active rectifier, while the synchronous rectification maintains a zero phase-shift behavior of the system.

In Fig. 10 the measurement results of the system efficiency as a function of the output power P_{out} are shown for tightly coupled inductors ($k = 0.6$), and for a system with relatively low coupling ($k = 0.3$). The plots compare the performance of the proposed control method to a conventional synchronous rectification approach. For the presented optimization concept, the phase-shift and the duty cycle have been controlled and for the synchronous rectification only the duty cycle has been adjusted during the measurement.

The experimental results show comparable trends as the simulations in Fig. 6, namely the proposed control strategy always achieves the same or a higher efficiency than a synchronous rectification approach. For a coupling factor $k = 0.6$ the efficiency of the examined system can be increased in the low power range (up to 4 W) yielding, e.g., an efficiency of 75% at an output power of $P_{\text{out}} = 1.8$ W compared to an efficiency of 71.2% for synchronous rectification. In the medium power range, between 4 and 7 W the efficiency does not increase significantly in

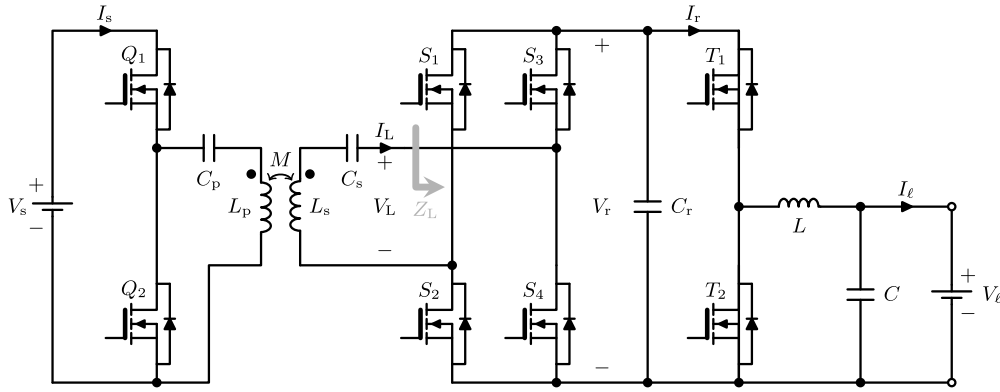

Fig. 8. Schematic illustration of the experimental setup. The discrete MOSFETs are controlled by an FPGA which implements the digital control architecture.

(b)

Fig. 9. Measurement of the key system waveforms for the proposed concept and a synchronous rectification approach at $k = 0.6$. (a) Waveforms of the rectifier input voltage V_L (3V/div) and input current I_L (600 mA/div) for the proposed concept with a phase-shift of $\varphi = 20^\circ$ and a duty cycle $D = 68\%$. (b) Waveforms of V_L (3V/div) and I_L (600 mA/div) for synchronous rectification with a duty cycle $D = 66\%$.

comparison to a synchronous rectifier. In case the output power is further increased, the proposed control method is again able to achieve a higher efficiency yielding, e.g., an efficiency of 69.4% at an output power $P_{out} = 8.2$ W compared to an efficiency of 66.4% with synchronous rectification. Furthermore, the amount of output power which can be extracted by the synchronous rectifier is limited to $P_{out} = 8.26$ W. A further increase of the input power P_{in} yields lower values of the output power P_{out}

due to the decrease in efficiency. In contrast, the proposed concept is able to extend the achievable output power of the system to 11.24 W, thus increasing the maximum achievable output power by 36%, while maintaining a high efficiency. For a lower coupling factor of $k = 0.3$ an even higher performance increase in terms of efficiency and extractable power can be obtained. The maximum output power of the system could be increased from 5.4 to 9.9 W (by 83%) when compared to a synchronous

rectification approach. Additionally, at every point of the operating range the achieved efficiency of the proposed approach is higher than for synchronous rectification. The measurement results of the prototyping setup clearly highlight the possibility of the proposed concept to extract more power while improving the efficiency of the system in comparison to a synchronous rectifier solution.

VI. CONCLUSION

In this study, a concept to achieve optimal efficiency for a desired amount of output power as well as to extend the power transfer capability of IPT systems has been presented. The proposed method is based on the adjustment of the equivalent load impedance as a function of the output power, which can be realized by introducing a phase-shift between current and voltage in the active rectifier, and by controlling the level of the rectified voltage. When operating exactly at resonance frequency the optimal equivalent impedance is purely resistive, and consequently the proposed approach behaves like a synchronous rectifier. If any deviation of the resonance frequency occurs, e.g., caused by parameter variations of the passive components, the presented concept achieves a superior performance.

The theoretical background of the proposed concept has been presented and validated by simulations as well as by experiments with the help of a WPT prototyping system based on the Qi standard. The results show that the efficiency of the system can be increased over the whole measurement range when compared to a synchronous rectifier. The performance gain increases for decreasing coupling factors. Furthermore, the maximum extractable output power of the prototyping system is raised by 36% for a coupling factor $k = 0.6$, and even by 83% for a coupling factor of $k = 0.3$, again in comparison to a synchronous rectification approach.

Andreas Berger (S'13) studied information technology at the Alpen-Adria University of Klagenfurt, Klagenfurt, Austria, with main focus on embedded systems, signal processing and control systems. In 2013, he finished the Master studies and joined the Embedded Systems and Signal Processing Group, University of Klagenfurt, working as a Researcher on the control of high efficient dc-dc converters. In September 2013, he joined the Institute of Signal Processing, Johannes Kepler University, Linz, Austria, where he is working toward the Ph.D. degree in cooperation with

the company Infineon Technologies Austria.

His research activities focus on the investigation of wireless power transfer and power management systems for mobile devices. In 2014, a collaboration with the Technical University of Madrid (Universidad Politécnica de Madrid, UPM) was established, where he investigates optimization strategies for wireless power transfer systems in the low and medium power range.

Matteo Agostinelli was born in Udine, Italy, in 1981. In 2006, he received the *Laurea Magistrale* (M.Sc.) degree in electrical engineering with honors from the University of Udine, Udine. In September 2008, he started working toward the Ph.D. degree at the Institute of Networked and Embedded Systems, University of Klagenfurt, Klagenfurt, Austria, in cooperation with Infineon Technologies, focusing on nonlinear control techniques for dc-dc converters.

From 2006 to 2008, he worked as a Research Assistant at the University of Udine, focusing on low-

power techniques for digital CMOS circuits and nanoscale innovative devices (multigate FETs, FinFETs). In September 2012, he joined Infineon Technologies, where he is currently working on the development of battery and power management mixed-signal ICs.

Mr. Agostinelli was the recipient of the Best Student Paper Award at IEEE MWSCAS 2010.

Sanna Vesti received the M.Sc. (Tech.) degree in electrical engineering in 2009 from the Tampere University of Technology, Tampere, Finland. In 2010, she got her second M.Sc. degree in industrial electronics from the Technical University of Madrid, Madrid, Spain, at the Center for Industrial Electronics where she started working toward the Ph.D. degree focusing on dynamic stability and robustness analysis of dc-distributed systems.

In October 2013, she joined Infineon Technologies, where she is currently working on the development of battery and power management mixed-signal ICs.

Jesús Á. Oliver (M'00) received the Master and Doctoral degrees in electrical engineering from the Technical University of Madrid (UPM), Madrid, Spain, in 1996 and 2007, respectively.

He became an Assistant Professor in 2001 and he is an Associate Professor at UPM since 2007. He has been author and coauthor in more than 150 scientific papers in journals and conferences and he holds three patents. His research activities include modeling (dc-dc converters, magnetic components, piezoelectric transformers, fuel-cells, and dc distributed

power electronic systems), fast control techniques for dc-dc converters for VRM applications and RF amplifiers, three-phase rectifiers for aircraft applications, wireless power transfer and power systems on chip. He has led numerous research projects with private and public funding and he has participated in more than 50 direct R&D projects with companies in Europe, US, Australia and China.

José A. Cobos (M'91-SM'12) received the Master's and Ph.D. degrees in electrical engineering from the Technical University of Madrid (UPM), Madrid, Spain, in 1989 and 1994, respectively. He is currently a Professor at the Technical University of Madrid (UPM), Madrid, Spain, since 2001. His contributions are focused in the field of power supply systems for telecom, aerospace, industrial, automotive and medical applications. His research interests include energy efficiency in digital circuits and RF amplifiers, magnetic components, piezoelectric transformers, trans-

cutaneous energy transfer and dynamic power management. He has advised 14 doctoral dissertations, published more than 200 technical papers, and holds six patents. He is the Director of the "Centro de Electrónica Industrial, CEI-UPM," a university research center, leading a strong industrial program in power electronics, with technology transfer through direct R&D contracts with more than 20 different companies in Europe, US, Australia and China. He has been cooperating with the IEEE and other professional associations (Reviewer, Session Chair, Topic Chair and Associate Editor).

Mr. Cobos received the "UPM Research and Development Award for Faculty Less Than 35 Years of Age," and the "Richard Bass Outstanding Young Power Electronics Award of the IEEE" (year 2000). Recently, he received the Semikron Innovation Award for the teamwork on "RF Power Amplifier With Increased Efficiency and Bandwidth." He has been awarded with one of the ten Google "Little Box Challenge" Awards, to develop the smallest possible inverter, for PV panels and high density batteries. Since 2003, he is serving as Associate Editor of the IEEE TRANSACTIONS ON POWER ELECTRONICS. From 2002 to 2005, he served as AE of the IEEE-PELS LETTERS. He is an AdCom Member of the IEEE Power Electronics Society and Member of the Steering Committee of IEEE-APEC.

Mario Huemer (M'00-SM'07) was born in Wels, Austria, in 1970. He received the Dipl.-Ing. degree in mechatronics and the Dr.techn. (Ph.D.) degree from the Johannes Kepler University of Linz, Linz, Austria, in 1996 and 1999, respectively.

From 1997 to 2000, he was a Research Assistant at the Institute for Communications and Information Engineering, University of Linz, Linz. From 2000 to 2002, he was with Infineon Technologies Austria, research and development center for wireless products.

From 2002–2004, he was a Lecturer at the University of Applied Sciences of Upper Austria, and from 2004–2007 he was Associate Professor for electronics engineering at the University of Erlangen-Nuremberg, Germany. In 2007, he moved to Klagenfurt, Austria, to establish the Chair of Embedded Systems and Signal Processing at Klagenfurt University as a Full Professor. From 2012 to 2013, he served as Dean of the Faculty of Technical Sciences. Since September 2013, he is Head of the newly founded Institute of Signal Processing, Johannes Kepler University of Linz. His research interests are adaptive and statistical signal processing, signal processing architectures and implementations, as well as mixed signal processing with applications in communications, radio frequency and baseband integrated circuits, battery and power management for mobile devices, sensor and biomedical signal processing. Within these fields he published more than 170 papers.

Dr. Huemer is Member of the IEEE Signal Processing Society, the IEEE Circuits and Systems Society, and the IEEE Communications Society. He is also Member of the German Society of Information Technology (ITG), and the Austrian Electrotechnical Association (OVE). In 2000, he received the German ITG and the Austrian GIT Award for dissertations, and in 2010 the Austrian Kardinal Innitzer Award in natural sciences. His review work includes national and European research projects as well as international journals. Since 2009, he is Member of the Editorial Board of the *International Journal of Electronics and Communications* (AEUE).
