Integral Attack on the Full FUTURE Block Cipher

Zeyu Xu, Jiamin Cui, Kai Hu*, and Meiqin Wang

i.e., SubCell, MixColumn, ShiftRow, and AddRoundKey. Unlike AES, it is a 64-bit-size block cipher with a 128-S-box is defined over \pmb{F}_{2^4} . The previous studies have shown that the integral properties of 4-bit S-boxes are **Abstract:** FUTURE is a recently proposed lightweight block cipher that achieved a remarkable hardware performance due to careful design decisions. FUTURE is an Advanced Encryption Standard (AES)-like Substitution-Permutation Network (SPN) with 10 rounds, whose round function consists of four components, bit secret key, and the state can be arranged into 16 cells. Therefore, the operations of FUTURE including its usually weaker than larger-size S-boxes, thus the number of rounds of FUTURE, i.e., 10 rounds only, might be too aggressive to provide enough resistance against integral cryptanalysis. In this paper, we mount the integral cryptanalysis on FUTURE. With state-of-the-art detection techniques, we identify several integral distinguishers of 7 rounds of FUTURE. By extending this 7-round distinguisher by 3 forward rounds, we manage to recover all the 128 bits secret keys from the full FUTURE cipher without the full codebook for the first time. To further achieve better time complexity, we also present a key recovery attack on full FUTURE with full codebook. Both attacks have better time complexity than existing results.

Key words: symmetric-key; integral attack; division property; FUTURE

1 Introduction

proposed by Gupta et al.^[1] It consists of 10 rounds and that accepts 128-bit key and has a block size of 64-bit. FUTURE is a new Substitution-Permutation Network (SPN)-based lightweight block cipher, recently is an Advanced Encryption Standard (AES)-like cipher

FUTURE is designed to encrypt data in a single clock cycle, i.e., an unrolled implementation. Therefore, the designers are committed to using very low implementation cost than other block ciphers in unrolled fashion. These lightweight algorithms, due to the high implementation cost, tend not to use the Maximum Distance Separable (MDS) matrix, although the MDS matrix provides better security under the same number of rounds. FUTURE overcomes this challenge by judiciously choosing a very lightweight MDS matrix. The MDS matrix is a composition of four sparse matrices, each matrix has very low implement cost. Meanwhile, the S-box is also obtained by composing four low-hardware-cost S-boxes. The authors benchmarked hardware implementations on Field Programmable Gate Array (FPGA) and Application Specific Integrated Circuit (ASIC) and compared FUTURE to several well-known lightweight ciphers in the literature with respect to size, critical path, and throughput. FUTURE ended up giving the

best results among the compared algorithms in many respects. The designer evaluated the security of FUTURE in the document. For differential and linear cryptanalysis, they expected that there would be no effective 5-round distinguisher. Later, Ilter et al. found effective 5-round differential and linear distinguishers in Ref. [2]. However, they did not further utilize distinguishers for key recovery attacks. Recently, Schrottenloher et al. utilized the Meet-in-the-Middle (MitM) technique to present the first full round key recovery attack of FUTURE^[3], breaking the designers' 7-round estimate under this technique.

The idea of integral attack comes from Square attack, which was first proposed by Daemon et al.^[4], and then formalized by Knudsen and Wagner[5] . It is one of the most powerful cryptanalysis techniques. Generally, it consists of an integral distinguisher and a key-recovery phase. During the construction of the integral distinguisher, a structure of plaintexts is encrypted to obtain a state set with integral property (e.g., zero-sum) in some positions. Then, the attacker guesses the relevant subkeys and partially decrypts the ciphertexts to the end of the distinguisher. The key space is reduced by checking the integral property.

Several techniques were proposed to optimize the integral attacks. The division property is the most efficient and accurate method of detecting integral distinguishers, which was introduced by Todo^[6] at EUROCRYPT 2015. It is word-oriented and can exploit the algebraic degree information of the local components. In particular, it was applied to MISTY1, and the full MISTY1 was broken for the first time^[7]. To better exploit the concrete structure of the ciphers, Todo and Morii[8] introduced the Bit-based Division Property (BDP) at FSE 2016. BDP treats the components of the target primitive at the bit level so that more information in the structures can be used. Compared with the word-based division property, the BDP is more likely to find better integral characteristics. Later, Wang et al.[9] presented the automatic methods to search for the three-subset bitbased division property effectively. In Ref. [10], Hao et al. introduced the three-subset bit-based division property without unknown subsets (3SDPwoU). The monomial prediction, proposed by Hu et al.^[12], is another language of division property from a pure algebraic perspective.

However, using common programming languages, the time and memory complexities for searching

division property in practice are $O(2^n)$ where *n* is the block size. To overcome this bottleneck, Xiang et al. combines the Mixed Integral Linear Programming (MILP) method and division property to search for the integral distinguishers at ASIACRYPT 2016[13] . As a result, they can deal with ciphers of block sizes much larger than 32 bits efficiently. Subsequently, some automatic searching tools aided by Boolean Satisfiability problem $(SAT)^{[14]}$ and Satisfiability Modulo Theories (SMT)^[15] are also proposed^[16, 17].

COPY, AND, and XOR have been modeled well in solve this problem, they are S method^[18], ZR method^[19], and H method^[20]. Among the three methods, S method cannot perfectly model the BDP ZR
1913
H Symmetric cryptographic primitives can be decomposed into a sequence of local building blocks. The propagations of division trails through these local components are modeled and the off-the-shelf solvers are called to find out whether there is a solution. If there is no solution, then balanced properties are found. Components such as S-boxes and basic operations like Ref. [13]. The BDP propagations of the linear layer can be easily handled thanks to these basic operations. However, the problem of how to efficiently model a complex linear layer, e.g., an MDS matrix, has remained. So far three methods have been proposed to propagations over a complex linear layer, while $Z\mathcal{R}$ method is only applicable to the so-called binary matrix. For the MDS matrix used in FUTURE, H method is then the only choice for a perfect model.

Our contributions. In this paper, we take state-ofthe-art techniques for detecting division properties to give a more fine-grained study of the security strength of the block cipher FUTURE against the integral attacks. To find more integral properties, we use the powerful model proposed by Hu et al.[20] to handle the linear layer of FUTURE. 7-round integral distinguishers are established for FUTURE. Based on the 7-round integral distinguisher, exploring the relationship between the round key bits in the key recovery phase, we manage to attack the full FUTURE without the full codebook for the first time. Futher, to achieve a better time complexity, we also present a key recovery attack on full FUTURE with full codebook. All the results are summarized in Table 1.

Outline. The paper is organized as follow. In Section 2, we briefly recall the automatic search problems of the BDP and methods to model linear layer. Next, in

Sections 3 and 4 we introduce the block cipher FUTURE and propose a integral distinguisher. We present two key recovery attacks on full FUTURE in Section 5.

2 Preliminary

2.1 Notations

We list the notations mainly used throughout this paper.

• Blackened italic lowercase letters (i.e., u, v, x): denote vectors in F_2^n ;

• $u[i]$ or u_i : denotes the *i*-th bit of a vector $u \in F_2^n$, where $u = (u_0, u_1, \ldots, u_{n-1}).$

 \bullet $u \cdot v$: denotes the inner product operation, $u \cdot v = \bigoplus_{i=0}^{n-1} u[i] \times v[i];$

• $u[i:j]$: $(j-i+1)$ -bit vector starting from $u[i]$ ending at $u[j]$, $i \le j$;

• M , M_1 , M_2 : denote *n* by *n* binary matrix;

• $M[i, j]$: denotes the entry of M located at the *i*-th row and *j*-th column;

• $M[i, *]$, $M[*, j]$: denote the *i*-th row of M and the *j*-th column of M .

2.2 (Bit-based) division property and automatic search models

The word-based division property^[6] was proposed by Todo originally as a generalization of integral attack. Subsequently, by shifting the propagation of the division property to the bit level, Todo and Morii[8] introduced the bit-based division property.

Definition 1 (Bit-based division property)^[8] Let X be a multiset whose elements belong to F_2^n . Let K be a multiset X has the division property \mathcal{D}_{K}^{n} , it fulfills the following conditions for any $u \in F_2^n$: $\bigoplus_{x \in X} \pi_u(x) =$ unknown if there exists a $k \in K$ s.t., $u \ge k$, and $\bigoplus_{x \in \mathcal{X}} u(x) = 0$ otherwise. $\pi_{\mathbf{x} \in X} \pi_{\mathbf{u}}(\mathbf{x}) = 0$ otherwise. set whose elements are n-bit bit vectors. When the

bitwise operations like XOR, AND and COPY. When these operations are applied to the elements in X , Many symmetric primitives are often composed of transformations of the division property should also be made following the propagation rules for XOR, AND and COPY which have been proved in Refs. [8, 13].

XOR^[8] Let the XOR operation create the output $y = x_0 \oplus x_1 \in \mathbf{F}_2$ from the input $x = (x_0, x_1) \in \{0, 1\}^2$, where $0 \le k_0, k_1 \le 1$. Assume the input multiset has the division property $\mathcal{D}^2_{(k_0,k_1)}$, then the corresponding output multiset has the division property $\mathcal{D}^1_{k_0+k_1}$, where $0 \leq i \leq k$.

For the BDP $k = (k_0, k_1)$ must satsify $0 \le k_0, k_1 \le 1$. If $k_0 = k_1 = 0$, i.e., the input division property is $\mathcal{D}_{(0,0)}^2$, then the output division property is \mathcal{D}_0^1 . If the input division property is $\mathcal{D}_{1,0}^2$ or $\mathcal{D}_{0,1}^2$, then the output division property is \mathcal{D}_1^1 . Moreover, y takes a value in F_2 , thus $0 \le k_0 + k_1 \le 1$ must hold, i.e., if $(k_0, k_1) = (1, 1)$, the division property propagation will XOR operation as $(x_0, x_1) \xrightarrow{\text{XOR}} y$ abort. We denote the division property propagation of operation as $(x_0, x_1) \longrightarrow y$.

 $\text{COPY}^{[8]}$ Let the COPY operation create the output $y = (y_0, y_1) \in \{0, 1\}^2$ from $x \in F_1$ as $y_0 = x$ and $y_1 = x$. \mathcal{D}_k^1 , then the corresponding output multiset has the division property $\mathcal{D}^2_{(i,k-i)}$ where $0 \le i \le k$. Assume the input multiset has the division property

The input multiset division property \mathcal{D}_k^1 must have $0 \le k \le 1$. If $k = 0$, the output multiset has the division property $\mathcal{D}_{(0,0)}^1$; otherwise, the output multiset has the division property $\mathcal{D}_{(0,1)(1,0)}^2$. We denote the division COPY $x \xrightarrow{\text{COPY}} (y_0, y_1)$ property propagation of the COPY operation as .

 $\mathcal{D}_{\bm{k} }^{1^n}$ of the chosen plaintexts, denoted by $\mathcal{D}_{K_0}^1$. Then the division property of the output ciphertexts at round r , $\mathcal{D}_{\bm{K}}^{1^n}$ denoted by $\mathcal{D}_{K_r}^{\Gamma_r}$, can be deduced according to the the attackers determine an index set $I \in \{0, 1, ..., n-1\}$ of the bit indices of the plaintext and prepare $2^{|I|}$ chosen plaintexts where the variables indexed by I take $\mathcal{D}_{\boldsymbol{k}}^{1^n}$ chosen plaintexts is $\mathcal{D}_k^{\mathbb{I}^n}$, where $k_i = 1$ if $i \in I$ and $k_i = 0$ otherwise. Then, the propagation of the division $\mathcal{D}_{\boldsymbol{k}}^{1^n}$ property from \mathcal{D}_k^{Γ} is evaluated as The attackers need to determine the division property round function and the propagation rules. Specifically, all possible values. The division property of such 164 *Tsinghua Science and Technology, February* 2025, 30(1): 161−170

$$
k=K_0\to K_1\to\cdots\to K_r,
$$

where \mathcal{D}_{K_i} is the BDP after the *i*-round propagation. If the division property K_r does not contain a unit vector e_i , then the *i*-th bit of the *r*-round ciphertexts is balanced.

2.3 Propagation of BDP in automatic search model

size of K_i increases rapidly. At Asiacrypt 2016, Xiang Finding the propagation of BDP is tedious because the et al.[13] showed that the propagation can be efficiently evaluated by using MILP. Firstly, they introduced the division trail as follows.

propagation of the division property ${k} = K_0 \rightarrow$ $K_1 \rightarrow \cdots \rightarrow K_r$. Moreover, for any vector $k_{i+1}^* \in K_{i+1}$, there must exist a vector $k_i^* \in K_i$ such that i_i^* can propagate to k_{i+1}^* by the propagation rule of the BDP $(k_0, k_1,..., k_r) \in (K_0 \times K_1 \times \cdots \times K_r)$, if k_i can propagate to k_{i+1} for all $i \in \{0, 1, \dots, r-1\}$, we call $(k_0 \rightarrow k_1 \rightarrow \cdots \rightarrow k_r)$ an *r*-round division trail. **Definition 2** (Division trail)^[13] Consider the for the current operation. Furthermore, for

The propagation of set K_i was transformed into the E_k be the target *r*-round cipher, if there is no division trail $0 \xrightarrow{E_k} k_r = e_i$, then there is no unit vector e_i in K_r , i.e., the *i*-th bit is balanced. So once all the unit vectors appear in K_{r+1} , there will be no balanced bits at the end of the $(r+1)$ -th round of E_k , and the maximum number cover is r rounds. propagation of the division trails by this definition. Let of rounds that integral distinguisher based on BDP can

2.4 New model for general linear layers

which have been considered by the S method^[18] an the $Z\mathcal{R}$ method^[19]. In this work, we use the new method For cipher with a bit-permutation linear layer like PRESENT, GIFT, etc., after the nonlinear layer, there is no cost for the BDP. The block cipher FUTURE has a non-bit-permutation linear layer, i.e., an MDS matrix, that proposed by Hu et al. to trace the BDP propagation^[20]. This method is accurate and effective for any type of matrices.

Proposition 1^[20] For a primitive matrix $M \in F_2^{n \times n}$, a division trail (u, v) is valid if and only if (u, v) meets the following constraints:

$$
E(i, j) \cdot v_j - \sum_{k=0}^{n-1} M(i, k) \cdot v_i \cdot u_k \cdot M_{\nu, u}^{\text{expand}'}(k, j) = 0,
$$

for $0 \le i, j \le n-1$, where E is an $n \times n$ identity matrix and $M_{v,u}^{\text{expand}} \in F_2^{n \times n}$ is an auxiliary matrix with n^2 elements.

3 FUTURE

FUTURE is an AES-like block cipher, the block size is 64 bits, and the master key length is 128 bits. It has a construction of 10 rounds in a fully unrolled fashion. The S-box and the MDS matrix are designed to be efficient in hardware.

of FUTURE are SubCell (SC), MixColumn (MC), ShiftRow (SR), and AddRoundKey (ARK). MC cipher is denoted by a 4×4 matrix S where each entry is a nibble; i.e., $s_i \in \mathbf{F}_2^4$ for $0 \le i \le 15$, **Round function.** The basic operations of each round operation is removed in the final round. The state of the

$$
X = \begin{bmatrix} s_0 & s_4 & s_8 & s_{12} \\ s_1 & s_5 & s_9 & s_{13} \\ s_2 & s_6 & s_{10} & s_{14} \\ s_3 & s_7 & s_{11} & s_{15} \end{bmatrix}.
$$

The round function is presented in Fig. 1.

SubCell. SubCell is a nonlinear transformation in which 4-bits S -box S is applied to every nibble of the state. *S* is a concatenation of four low hardware cost Sboxes. The hexadecimal notation are given by the following Table 2.

MixColumn. The MixColumn is a linear operation column of the state. FUTURE use an MDS matrix M_1 $GF(2^4) = GF(2)/\langle x^4 + x + 1 \rangle$. Assert α is a root of $x^4 + x + 1$, we have that operates separately on each column of the four for this operation. The multiplication is over finite field

$$
M_1=\left[\begin{array}{cccc} \alpha^3 & \alpha^3+1 & 1 & \alpha^3 \\ \alpha+1 & \alpha & \alpha^3+1 & \alpha^3+1 \\ \alpha & \alpha+1 & \alpha^3 & \alpha^3+1 \\ \alpha^3+1 & \alpha^3+1 & \alpha^3 & 1 \end{array}\right],
$$

and

Fig. 1 Round function.

Table 2 S-box of FUTURE.

for $i = 0, 4, 8, 12$.

ShiftRow. ShiftRow rotates row *i* of the array state *i* nibble positions to the right,

 $AddRoundKey.$ The 64 -bit round key RK_i is XORed to the state at round i of the cipher. And the 64-bit whitening key WK is XORed to the plaintext of the cipher.

Key scheduling. Future uses 128-bit master key *K*. It splits K into two 64-bit parts for whitening key and the first round key, i.e., $K = WK||RK_1$. Then the round key RK_i ($2 \le i \le 10$) generation is as follow:

$$
RK_i = \begin{cases} WK \ll \left(5 \times \frac{i}{2}\right), & \text{if } 2 \mid i; \\ RK_1 \ll \left(5 \times \left\lfloor \frac{i}{2} \right\rfloor\right), & \text{if } 2 \nmid i. \end{cases}
$$

Obviously, RK_i is a 64-bit permutation in WK or $RK₁$ without any bit operations.

MC and SR are invertible linear operations, so the ARK operation can be moved before the MC operation. The new round key EK_i is the equivalent round key, which is obtained by performing the inverse operation of SR and MC in turn, i.e., $EK_i = MC^{-1} \circ SR^{-1}(RK_i)$. Therefore, there exists a 64 order binary invertible matrix M_2 such that $EK_i = M_2 \times RK_i$. The equivalent **Round function (Equivalent key).** Note that both round function is shown in Fig. 2.

4 Distinguisher

By choosing a proper initial BDP, we find 7-round integral distinguisher. The distinguisher with 63 active bits in the plaintexts and full balanced bits in the ciphertexts, is given as below

Fig. 2 Equivalent round function.

For example, if the plaintext set is $\{1||A \mid A = F_2^{63}\}\)$ or $\{0\|A\|A = F_2^{63}\}\$, then the ciphertext set obtained by encrypting 7 rounds is balanced on 64 bits.

5 Key-Recovery Attack on Full FUTURE

5.1 Key-recovery attack on full future without full data

after the 7-round distinguisher in Section 4, we can give a key recovery attack on full (10-round) we guess round keys' cells in equivalent keys EK_8 , EK₉, and EK₁₀ instead of K_8 , K_9 , and K_{10} , where $EK_i = MC^{-1} \circ SR^{-1}(K_i), i \in \{7, 8, 9\}.$ In this subsection, we propose a key recovery attack on full FUTURE without full data. By adding three rounds FUTURE, which is presented in Fig. 3. In our attack,

with the form of $C^1 \mathcal{A}^{63}$, each cell in X_8 is balanced $(X_8[0])$. Therefore, the whole attack includes a data ciphertext C in the set to $X_8[0:3]$ by guessing some cells in EK_8 , EK_9 , and EK_{10} , and then filter out the wrong key based on the balance of $X_8[0:3]$. Detailed As shown in Fig. 3, when encrypting a plaintext set collection phase and a key recovery phase. During the data collection phase, we remain the ciphertext set obtained by encrypting the plaintext set mentioned above During the key recovery phase, we decrypt each steps of attack are given as follows.

plaintext set has the form $C^1 \mathcal{A}^{63}$, which means the size of set is 2^{63} . After accessing all plaintext in the set to the 10-round encryption machine, we remain the returned ciphertext in set C with the size of 2^{63} . In this phase, the time complexity is 2^{63} 10-round **Data collection.** According to the distinguisher, the encryptions.

 $X_8[0:3]$. In order to decrypt ciphertext C to $X_8[0:3]$, need to guess EK_{10} , $EK_{9}[0, 5, 10, 15]$, and $EK_{8}[0:3]$. **Key recovery.** We focus on checking the balance of we need to know all the gray cells in Fig. 3, that is, we However, according to the key scheduling, we have

$$
EK_{10} \xrightarrow{SR^{-1} \circ MC^{-1}} K_{10} \xrightarrow{\ggg 5} K_8 \xrightarrow{MC \circ SR} EK_8,
$$

which indicates that EK_8 can be deduced from EK_{10} . Algorithm 1 provides a brief description of the key recovery procedure. The detailed attack procedure is as follows.

(1) **Steps 1 to 6.** Guess EK_{10} and compute $Z_9[0, 5, 10, 15]$ under 2^{63} plaintexts C. According to Fig. 3,

Algorithm 1 10-round key recovery attack

2 Allocate and initialize the arrays $V_1[x]$ with $|x| = 16$;

1 for each EK_{10} do

4 **for** *C* in *C* **do**

3 Deduce EK_8 from EK_{10} ;

5 Compute *Z*9[0, 5, 10, 15] ;

 $Z_9[10] \leftarrow \text{MC}^{-1}(W_9[8:11]),$

 $Z_9[15] \leftarrow \text{MC}^{-1}(W_9[12:15]).$

Remain the value of $Z_9[0, 5, 10, 15]$ in V_1 for the next decryption step. Note that in V_1 , only the even and odd of the occurrence number of $Z_9[0, 5, 10, 15]$ is recorded (0 refers to even, 1 refers to odd), because even times of a value will not affect the balance. This step requires

$$
2^{64} \times 2^{63} \times \frac{1}{10} \approx 2^{123.7}
$$

10 -round encryptions. And the memory complexity of this part is 2^{16} bits.

(2) **Steps 6 to 13.** Guess $EK_9[0, 5, 10, 15]$ and compute $X_8[0:3]$ under $Z_9[0, 5, 10, 15]$ with $V_1[Z_9[0, 5, 10, 15]] == 1$. Note that EK_8 can be deduced from EK_{10} . Compute sum by operating bitbased XOR for all $X_8[0:3]$. This step requires

$$
2^{64} \times 2^{16} \times 2^{16} \times \left(\frac{4}{16} + \frac{4}{16}\right) \times \frac{1}{10} \approx 2^{91.7}
$$

10-round encryptions.

(3) **Steps 13 to 17.** From a random perspective, there are $2^{64} \times 2^{16} \times 2^{-16} = 2^{64}$ (EK₁₀, EK₉[0, 5, 10, 15]) that satisfy $sum = 0$, and the correct key must be among them. Then guess $EK_9[1, 2, 3, 4, 6, 7, 8, 9, 11, 12, 13,$ 14] and deduce master key K under each $(EK_{10},$ **Steps 13 to 17.** From a random perspective, there

W_9 = \text{SR}^{-1}(\text{MC}^{-1} \circ \text{SR}^{-1}(C) \oplus \text{EK}_{10}),
$$

\n
$$
Z_9[0] \leftarrow \text{MC}^{-1}(W_9[0:3]),
$$

\n
$$
Z_9[5] \leftarrow \text{MC}^{-1}(W_9[4:7]),
$$

EK9[0, 5, 10, 15]) . Extract plaintext-ciphertext pair (p, c) from the data and obtain the correct key by verifying whether $E(K, p)$ is equal to c. This step requires $2^{64} \times 2^{48} = 2^{112}$ 10-round encryptions.

Complexity. The 10-round attack requires a data complexity of 2^{63} chosen plaintexts. The time complexity is $2^{63} + 2^{123.7} + 2^{91.7} + 2^{112} \approx 2^{123.7}$ 10-round encryptions. The memory complexity is 2^{16} bits.

5.2 Key-recovery attack on full FUTURE with full data

In this subsection, we propose a key recovery attack on full FUTURE with full data. By adding one round before and two rounds after the 7-round distinguisher in Section 4, we can give a key recovery attack on full (10-round) FUTURE. The time complexity of this attack is currently the lowest.

when the Z_1 set obtained by encrypting the plaintext set has the form $C^1 \mathcal{A}^{63}$, each nibble in X_9 is balanced (i.e., *X*9[0]). Therefore, the whole attack includes a data As shown in Fig. 4, assuming we have a plaintext set,

WK *P*

Then we decrypt each ciphertext C in the set to $X_9[0:3]$ by guessing some bits in EK₉ and EK₁₀, and *X*9[0 : 3] . Detailed steps of attack are given as follows. collection phase and a key recovery phase. During the data collection phase, we remain the ciphertext set obtained by encrypting full plaintext. During the key recovery phase, we choose the corresponding ciphertext set based on guessing the whitening key. then filter out the wrong key based on the balance of

attack. The time complexity is 2^{64} 10-round encryptions, and the memory complexity is $2^{64} \times 64 =$ 2^{70} bits. Note that the ciphertext are stored in a 2^{16} by 2^{48} two-dimensional list S , The index of the first dimension corresponds to some cells of the plaintext P , this is, $S[P[0:3]] = \{E(K, P[0:3]||x) | x \in \mathbf{F}_2^{48}\}.$ **Data collection.** All ciphertext are used in this

 $X_9[0:3]$ under the assumption that the set of X_2 has the form $C^1 \mathcal{A}^{63}$. Therefore, we need to ensure that the X_2 $C^1 \mathcal{A}^{63}$, then decrypt the corresponding ciphertext set to **Key recovery.** We focus on checking the balance of set obtained by encrypting the plaintext set has form

Fig. 4 10-round key recovery attack.

get the X_9 set. Note that $Z_1 = \text{MC}(EK_1) \oplus \text{SR}^{-1}(X_2)$, where SR^{-1} does not affect the first block of X_2 and $MC(EX_1)$ is a constant. Thus, the Z_1 set also has the form $C^1\mathcal{A}^{63}$, denoted by

$$
\{0||A||B\mid A = \mathbf{F}_2^{15}, B = \mathbf{F}_2^{48}\}.
$$

Furthermore, we obtain the plaintext set

 $\{(WK[0:3] \oplus SC^{-1} \circ MC^{-1}(0||A))||B\}.$

This indicates that given the Z_1 set, the plaintext set is determined by $WK[0:3]$. And $WK[0:3]$ only denotes $P[0:3]$, and each $P[0:3]$ corresponds to $2^{48} P[4:15]$. The ciphertext set under each $P[0:3]$ can be obtained by using the list S obtained during the data collection phase.

 $EK_{10}[0, 5, 10, 15]$ and $EK_{9}[0:3]$ to obtain the set of *X*9[0 : 3] . According to the key scheduling, there exists a 64th order full rank binary matrix M such that $EK_{10} = M \times WK$, while EK_9 is independent of WK. Set the unknown bit in $WK(WK[4:15])$ to 48 variables $\mathbf{x} = [x_1, x_2, \dots, x_{48}]^\text{T}$, and use $[M_L|M_R]$ to record the After obtaining the ciphertext set, we guess following matrix:

\n $M_{0,0}$ \n	\n $M_{0,15}$ \n	\n $M_{0,16}$ \n	\n $M_{0,63}$ \n					
\n $\begin{bmatrix}\n M_{3,0} & \cdots & M_{3,15} \\ M_{20,0} & \cdots & M_{3,15} \\ M_{20,0} & \cdots & M_{20,15}\n \end{bmatrix}$ \n	\n $M_{3,16}$ \n	\n $\begin{bmatrix}\n M_{3,16} & \cdots & M_{3,63} \\ M_{20,16} & \cdots & M_{20,63} \\ M_{23,0} & \cdots & M_{23,15} \\ M_{23,0} & \cdots & M_{23,15} \\ M_{40,0} & \cdots & M_{40,15}\n \end{bmatrix}$ \n	\n $M_{23,16}$ \n	\n $\begin{bmatrix}\n M_{23,16} & \cdots & M_{23,63} \\ M_{40,16} & \cdots & M_{40,63} \\ \vdots & \ddots & \vdots \\ M_{43,0} & \cdots & M_{43,15} \\ M_{60,0} & \cdots & M_{60,15}\n \end{bmatrix}$ \n	\n $M_{43,16}$ \n	\n $\begin{bmatrix}\n M_{43,16} & \cdots & M_{43,63} \\ M_{60,16} & \cdots & M_{60,63} \\ \vdots & \ddots & \vdots \\ M_{63,0} & \cdots & M_{63,15}\n \end{bmatrix}$ \n	\n $M_{63,16}$ \n	\n $\begin{bmatrix}\n M_{63,16} & \cdots & M_{63,63}\n \end{bmatrix}$ \n

we can get the following system of linear equations containing 16 equations and 48 variables:

$$
[M_L|M_R] \times \left[\begin{array}{c} \hbox{WK[0]}\\ \hbox{WK[1]}\\ \hbox{WK[2]}\\ \hbox{WK[3]}\\ \hline \end{array}\right]_{64\times 1} = \left[\begin{array}{c} \hbox{EK}_{10}[0] \\ \hbox{EK}_{10}[5] \\ \hbox{EK}_{10}[10] \\ \hbox{EK}_{10}[15] \end{array}\right]_{16\times 1},
$$

Then, we have

$$
M_R \times x = \begin{bmatrix} \nEK_{10}[0] \\ \nEK_{10}[5] \\ \nEK_{10}[10] \\ \nEK_{10}[15] \n\end{bmatrix} \oplus M_L \times \begin{bmatrix} \nEK_{10}[0] \\ \nEK_{10}[5] \\ \nEK_{10}[10] \\ \nEK_{10}[15] \n\end{bmatrix} = b.
$$

equations, only when $rank(M_R) = rank([M_R|b])$, the space is $2^{48 - \text{rank}(M_R)}$. According to the theory of nonhomogeneous linear equations have solutions, and the size of the solution

M^L = 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0 0 0 1 0 1 0 0 0 1 1 0 0 0 0 0 1 0 0 0 1 0 1 0 0 0 1 1 0 1 0 0 1 1 0 0 1 0 0 1 0 0 0 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1 0 0 1 0 0 0 0 1 0 0 1 1 0 0 0 1 1 0 0 1 0 0 0 0 1 0 0 1 1 0 0 0 1 1 0 0 1 0 0 0 0 1 0 0 1 1 0 ,

and

,

$$
M_R=\left[\begin{smallmatrix} 1&1&0&1&0&1&0&0&1&0&0&0&0&0&0&0&1&0^22\\ 0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0^32\\ 0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0^32\\ 0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0^32\\ 1&1&0&0&1&1&0&0&0&1&1&0&0&0&0&0^32\\ 0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0^32\\ 0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0^32\\ 0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0^32\\ 1&0&0&0&0&0&0&1&1&0&0&1&0&0&0^32\\ 1&0&0&0&1&1&0&0&1&0&0&1&0&0&0^32\\ 0&1&0&0&0&1&1&0&0&1&0&0&1&0&0^32\\ 0&0&1&0&0&0&1&0&0&1&0&0&0&1&0^32\\ 0&0&1&0&0&1&1&0&0&1&0&0&0&0&0^32\\ 0&0&0&1&0&0&1&0&1&1&0&0&1&0&0&0^32\\ 0&0&0&1&0&0&1&1&0&1&1&0&0&1&0&0&0^32\\ 1&0&0&1&1&0&0&0&0&0&1&1&0&1&0&0&10&0^32\\ \end{smallmatrix}\right]
$$

where $\mathbf{0}^i$ is *i*-bit zero vector. Obviously, rank $(M_L) = 6$ and rank $(M_R) = 10$. There are 6 zero lines in M_R , which means **Therefore, given** $WK[0:3], EK_{10}[0, 5, 10, 15]$ has 6 bits constraints, then 2^{10} EK₁₀[0, 5, 10, 15] satisfy the equation with solutions. And the solution space size of x is $2^{48-10} = 2^{38}$. Based on the key relationship obtained above, we briefly introduced the key recovery procedure in Algorithm 2. The detailed attack procedure is as follows.

(1) **Steps 1 to 5.** Guess $WK[0:3]$ and compute *P*[0 : 3] under $2^{15} Z_1[0:3]$. Remain the value of *P*[0 : 3] in S_1 as indexes for ciphertext list S . This step requires

$$
2^{16} \times 2^{15} \times \frac{4}{16} \times \frac{1}{10} \approx 2^{25.7}
$$

10 -round encryptions. And the memory complexity of this part is $2^{15} \times 16 = 2^{19}$ bits.

(2) **Steps 7 to 13.** Guess $EK_{10}[0, 5, 10, 15]$ and matrix-vector multiplication is $2^{16} \times 2^{16} \times 6 \times 16 = 2^{41.6}$. This step will remain $2^{16-6} = 2^{10}$ EK₁₀[0, 5, 10, 15]. Then compute $Z_9[0:3]$ under ciphertext set obtained by S_1 and S . As in Algorithm 2, V_1 record the parity of the number of occurrences of $Z_9[0:3]$. Meanwhile, check whether satisfy the constraint. The complexity of

Zeyu Xu et al.: *Integral Attack on the Full FUTURE Block Cipher* 169

	Algorithm 2 10-round key recovery attack with full data
	1 for 2^{16} WK[0 : 3] do
$\overline{2}$	Allocate and initialize the set S_1 ;
3	for $2^{15} Z_1[0:3]$ do
4	Compute $P[0:3] = WK[0:3] \oplus SC^{-1} \circ MC^{-1}(Z_1[0:3])$;
5	Append $P[0:3]$ to S_1 ;
6	for 2^{16} EK ₁₀ [0, 5, 10, 15] do
7	if $EK_{10}[0, 5, 10, 15]$ and $WK[0:3]$ satisfy the constraints then
8	Allocate the set S_2 containing the basic solutions of 2^{38} WK[4 : 15] deduced by WK[0 : 3] and $EK_{10}[0, 5, 10, 15];$
9	Allocate and initialize the arrays $V_1[x]$ with $ x = 16$;
10	for $2^{15} P[0:3]$ in S_1 do
11	for 2^{48} C related to $P[0:3]$ do
12	Compute $Z_9[0:3]$;
13	Let $x = Z_9[0:3]$ and $V_1[x] = V_1[x] \oplus 1$;
14	for 2^{16} EK ₉ [0 : 3] do
15	Allocate and initialize the 16-bit variable sum;
16	for $x = 0$; $x < 2^{16}$; $x + +$ do
17	if $V_1[x] == 1$ then
18	Compute $X_9[0:3]$ from $Z_9[0:3] = x$;
19	$sum = sum \oplus X_9[0:3];$
20	if $sum == 0$ then
21	for 2^{48} EK ₉ [4 : 15] do
22	for 2^{32} WK[4 : 15] generated by the basic
	solutions in S_2 do
23	Deduce master key K ;
24	if $E(K, p) == c$ then
25	return K ;

 S_2 contains 2^{38} possible values of WK, which are obtained by solving the equation system. This step requires

$$
2^{16} \times 2^{10} \times 2^{15} \times 2^{48} \times \frac{4}{16} \times \frac{1}{10} \approx 2^{83.7}
$$

10 -round encryptions. The complexity of Gaussian Elimination is $O(2^{16} \times 2^{10} \times 10^3) = O(2^{36})$. And the memory complexity of this part is $|V_1| + |S_2| = 2^{16} +$ $39 \times 48 = 2^{16.1}$ bits.

(3) **Steps 14 to 19.** Guess $EK_9[0:3]$ and compute $X_9[0:3]$ under $Z_9[0:3]$ with $V_1[Z_9[0:3]] == 1$. Compute sum by operating bit-based XOR for all *X*9[0 : 3] . This step requires

$$
2^{16} \times 2^{16} \times 2^{16} \times 2^{16} \times \frac{4}{16} \times \frac{1}{10} \approx 2^{58.7}
$$

10-round encryptions.

(4) **Steps 20 to 25.** From a random perspective, there are $2^{16} \times 2^{-16} = 1$, $EK_9[0:3]$ that satisfy sum = 0, and $EK_9[4:15]$ and deduce master key K under each WK generated by the basic solutions in S_2 . Extract plaintext-ciphertext pair (p, c) from the data and obtain the correct key by verifying whether $E(K, p)$ is equal to *c* . This step requires **Steps 20 to 25.** From a random perspective, there the correct key must be among them. Then guess

$$
2^{16} \times 2^{10} \times 2^{16} \times 2^{-16} \times 2^{48} \times 2^{38} = 2^{112}
$$

10-round encryptions.

Complexity. This 10-round attack requires a data complexity of 2^{64} . The time complexity is 2^{112} 10round encryptions. The memory complexity is $2^{16.1}$ bits.
