ABSTRACT With the advance of gyro technology, modern gyros have two output types: angular rate or integrated angular rate. However, the conventional sculling velocity algorithms usually still adopt integrated angular rate/specific-force increments as algorithm inputs. So the engineer must convert the angular rate into integrated angular rate by digital integration to use them. This step will produce non-negligible computational error. To solve this issue, we proposed two types of novel optimal sculling algorithms using angular rate input. The advantage of the novel algorithms is that they can directly calculate out the carrier velocity without converting the angular rate of gyro output into integrated angular rate. Hence, they have a higher accuracy than the conventional sculling algorithms. The results of digital simulations also demonstrate this conclusion.

INDEX TERMS Strapdown inertial navigation algorithm, velocity algorithm, sculling algorithm, coning algorithm, specific-force transformation

NOMENCLATURE

\begin{align*}
f &= \text{specific-force measured by accelerometers} \\
C_{ib} &= \text{direction cosine matrix} \\
H &= \text{update period} \\
h &= \text{subminor interval in one update period} \\
\Delta \theta_i &= \text{incremental angle vector over the } i\text{th subminor interval} \\
\omega_{A1A2} &= \text{angular rate of coordinate frame } A2 \text{ relative to coordinate frame } A1 \text{ projected on } A3 \text{ frame axe; when } A1 \text{ is the inertial frame, } \omega_{A1A2} \text{ is the angular rate measured by angular rate sensors mounted on frame } A2
\end{align*}

I. INTRODUCTION

A. RELATED RESEARCH WORK

Nowadays, strapdown inertial navigation systems (SINS) such as being installed on a high-speed unmanned surface vehicle (USV), often work in a high dynamic environment. To assess the performance of the navigation algorithms used in SINS, some standard carrier motions are employed. For example, coning motion is the standard input to assess the performance of the strapdown attitude algorithm, sculling motion is the standard input to assess the performance of the strapdown velocity algorithm under highly dynamic environments. To improve the navigation accuracy of SINS in the high dynamic environment, many scholars conducted numerous researches. Among them Savage is the most outstanding scholar. He provided an analytical description of sculling motion and proposed a collection of algorithms which can precisely calculate the coning correction and the sculling correction [1][2]. He also give an analytical model for the evaluation of error build-up under band-limited random process input for the digital integration coning and sculling algorithm [3-4]. It was demonstrated that the digital integration process introduced a random walk type error in the output that was directly proportional to the root-mean-square input amplitude, directly proportional to the square-root of the input bandwidth, and inversely proportional to the digital integration update frequency. Ignagni is another famous scholar. He derived a class of optimized sculling
algorithms and demonstrated a duality between the derived class of sculling algorithms and the class of coning algorithms [5-7]. Roscoe proposed a generic equivalency between coning and sculling integrals and algorithms. Following his method, it is easy to obtain a sculling algorithm from the corresponding coning algorithm based on incremental angle input by adopting a simple mathematical formula [8]. In Ref. 9 two alternative approaches were developed for deriving strapdown navigation sculling algorithms. A key point of the two approaches is the uses of additional gyro/accelerometer output signals which are the increments of the angular-rate/specific-force multiple integrals over the iteration interval to improve the algorithm accuracy. Song employed Taylor series expansion to analyze the error of the conventional sculling correction algorithm under maneuvers, he proposed some new sculling algorithms which are constructed with the presented sculling algorithms for the velocity translation vector, and avoid the loss in accuracy of velocity translation vector under maneuvers [10-11].

B. KEY WORK OF THIS PAPER

These conventional sculling velocity algorithms are all based on the assumption that the output of gyro is integrated angular rate. However, modern inertial sensors produce different types of output now. For example, the micro-electromechanical systems (MEMS) gyro and some kinds of fiber optical gyro (FOG) have angular rate sampled output, not integrated angular rate. So, the conventional sculling velocity algorithms are not well-suited for the SINS which are equipped with a FOG or a MEMS gyro. In addition, at the present the accelerators also have different output types, for example, the quartz accelerometer output is usually specific-force, but some other types of accelerometer output specific-force increments.

In order to adapt to this tendency, we designed two types of optimal sculling velocity algorithms based on angular rate input. The first type of algorithms uses the angular rate/specific-force as the algorithm inputs. The second uses the angular rate/specific-force increments as algorithm inputs. These novel algorithms can directly calculate out the carrier velocity without converting the dimension of gyro’s output. Therefore, for the SINS equipped with a gyro with the output of angular rate, the precision of the algorithm can be improved considerably.

II. ALGORITHM EXAMPLES FOR CONVENTIONAL SCULLING ALGORITHMS

Velocity rate equation is [1]:

\[ \dot{V} = C_\theta f - (2\omega_n^* + \omega_n^{ie}) \times V^* + g^* \]  

(1)

where \( g^* \) is the gravitational acceleration projected on “\( n \)” frame axe (navigation coordinate). The subscripts “\( i \), \( e \), \( n \)” in \( \omega \) represent the inertial coordinate, geographic coordinate, and navigation coordinate respectively. “\( V^* \)” is the carrier velocity. The body’s velocity in navigation coordinates at time \( t_n \) is then obtained as the integral of Eq.(1) from time \( t_{n-1} \), evaluated at time \( t_n \):

\[
V^n_n = V^n_{n-1} + \int_{t_{n-1}}^{t_n} \left[ g^* - (2\omega_n^* + \omega_n^{ie}) \times V^n_{n-1} \right] dt
\]

(2)

where \( m \) is the digital velocity integration algorithm update rate computer cycle index, \( \Delta V_{gin} \) is the integrated transformed specific-force increment, \( \Delta V_{g/corn} \) is the gravity/Coriolis velocity increment. \( g^* \), \( \omega_n^* \) in \( \Delta V_{g/corn} \) can be assumed as constants. Hence \( \Delta V_{g/corn} \) in Eq. (2) can be calculated approximately as a constant during one update period. \( \omega_n^* \) is almost no variation during \( (t_{n-1}, t_n) \) so it can be derived from the \( V^n_{n-1} \), which is the carrier velocity at \( t_{n-1} \) and has been calculated out during the last velocity determination iteration. The \( \Delta V_{g/corn} \) calculation includes solving for an integral that represents the change in velocity caused by specific-force acceleration (Ref. 1, Eq.(26)):

\[
\Delta V_{g/corn} = \int_{t_{n-1}}^{t_n} (\Delta \theta(t) \times f(t)) dt
\]

(3)

where:

\[
\Delta \theta(t) = \int \omega(t) dt, \quad \Delta V_n = \int_{t_{n-1}}^{t_n} f(t) dt
\]

(4)

Then, Eq. (3) can be written as [see Ref. 1, Eqs. (27–36) for development]:

\[
\Delta V_{g/corn} = \Delta V_n + \frac{1}{2} \Delta \omega_n \times \Delta V_{n-1} + \frac{1}{2} \int_{t_{n-1}}^{t_n} (\Delta \theta(t) \times f(t) + \Delta V(t) \times \omega(t)) dt
\]

(5)

where \( \Delta V_{rotm} \) is the velocity rotation correction and \( \Delta V_{sculm} \) is the sculling correction. Obviously, there is:

\[
\Delta V_{sculm} = \frac{1}{2} \int_{t_{n-1}}^{t_n} [\Delta \theta(t) \times f + \Delta V(t) \times \omega(t)] dt
\]

(6)

The discrete algorithm of \( \Delta V_{sculm} \) can be converted from coning algorithm using a simple duality formula[5, 8]. For example, the 2-interval optimal sculling algorithm using incremental angle/specific-force increments inputs is [5, 8]:

\[
\Delta \hat{V}_{sculm} = \frac{2}{3} (\Delta \theta_1 \times \Delta V_2 + \Delta V_1 \times \Delta \theta_2)
\]

(7)

Its coning algorithm counterpart, namely the 2-interval optimal coning algorithm using incremental angle input is[1, 5]:

\[
\Delta \hat{\Phi} = \frac{2}{3} (\Delta \theta_1 \times \Delta \theta_2)
\]

(8)

The 3-interval optimal sculling algorithm is [5, 8]:

\[
\Delta \hat{V}_{sculm} = \frac{2}{3} (\Delta \theta_1 \times \Delta V_2 + \Delta V_1 \times \Delta \theta_2)
\]

(9)
\[ \Delta \tilde{V}_{\text{sculin}} = (\frac{9}{20} \Delta \theta + \frac{27}{20} \Delta \omega) \times \Delta V_i + (\frac{9}{20} \Delta V_i + \frac{27}{20} \Delta V_i \times \Delta \theta) \times \Delta \omega \]  

(9)

Its coning algorithm counterpart, namely the 3-interval optimal coning algorithm [5, 8]:

\[ \Delta \Phi = (\frac{9}{20} \Delta \omega + \frac{27}{20} \Delta \omega \times \Delta \theta) \times \Delta \omega \]  

(10)

### III. SCULLING ALGORITHM USING ANGULAR RATE/SPECIFIC-FORCE INPUT

There are two imperfections in the conventional sculling velocity algorithms such as Refs. 5 and 8. Firstly, strictly speaking, only with the duality between coning integral and sculling integral we can’t obtain the optimal coefficients for the sculling integration algorithm. To obtain the optimal coefficients, the duality between true coning correction and true sculling correction also needs to be demonstrated. Secondly, as is seen in Eqs.(7) and (10), the conventional sculling algorithm adopts the integrated angular-rate/specific-force increments as input. But with the development of inertial sensors, many inertial measurement units (IMU) have the output of angular rate now. In such cases the conventional sculling algorithms can’t calculate the body’s velocity accurately. To use the conventional velocity algorithms, we must convert the angular rate into incremental angle by digital integration in order to use Eq.(7) or Eq.(9). Obviously, this step will cause the non-negligible computational error. To solve this problem, we proposed two types of formalized optimal sculling algorithm based on angular rate input in this paper. The first type is the optimal sculling algorithm based on angular rate/specific-force inputs. The derivation process is based on the duality between the coning integral and the sculling integral as well as the duality between true coning correction and true sculling correction.

#### A. THE DUALITY BETWEEN THE GENERIC CONING INTEGRAL AND SCULLING INTEGRAL

Let us define \( \Delta \tilde{V}_{\text{sculin}} \) to be a digital integration algorithm for sculling correction, \( \hat{\Phi} \) be a digital integration algorithm for coning correction. Ref. 5 has demonstrated the duality equivalency between the generic coning integral and sculling integral. The demonstration details in Ref. 5 can be seen in Appendix. From Ref. 6 (Eq.(25)) we can obtain the generic coning integral term using angular rate input:

\[ \hat{\Phi} = \sum_{j=1}^{N} \sum_{i=0}^{N-1} K_{ij} (\omega_i \times \omega_j) H^2 \]  

(11)

where \( K_{ij} \) is the constant coefficients which will be optimized under coning motion, \( \omega_i \) is the angular rate sample of \( i \)th moment in one iteration interval. Based on duality principle, from Eq.(A12) in Appendix we can obtain:

\[ \Delta \tilde{V}_{\text{sculin}} = \sum_{j=1}^{N} \sum_{i=0}^{N-1} K_{ij} (\omega_i \times \omega_j \times H^2 \times \Delta \omega \times \Delta \Phi \times \Delta \omega) \]

\[ = \sum_{j=1}^{N} \sum_{i=0}^{N-1} L_{ij} (\omega_i \times \omega_j \times H^2 \times \Delta \omega \times \Delta \Phi \times \Delta \omega) \]

(12)

where \( L_{ij} \) is the unknown coefficient which should be optimized under sculling motion.

#### B. THE DUALITY BETWEEN TRUE CONING CORRECTION AND TRUE SCULLING CORRECTION

However, only from the duality between the generic coning integral and the generic sculling integral in Ref.5 we can’t obtain the optimal coefficients for the sculling integration algorithm. To obtain the optimal coefficients, the duality between true coning correction and true sculling correction also needs to be demonstrated.

A typical sculling motion is defined as:

\[ \omega = b \Omega \cos(\Omega t) J, f = c \sin(\Omega t) K \]  

(13)

where \( b \) is the amplitude of the angular vibration, \( c \) is the amplitude of the specific-force vibration, \( J, K \) are the unit vectors along the two body axes \( y, z \) about which the oscillations are occurring, and \( \Omega \) is the frequency associated with the angular and specific-force oscillations. Substituting Eq.(13) into Eq.(6) gives the true sculling correction:

\[ \Delta V_{\text{sculin}} = \frac{1}{2} \int_{t_{n-1}}^{t_n} [\Delta \theta (t) \times f + \Delta V (t) \times \omega] \, dt \]  

\[ = \frac{bc}{2} (H - \frac{1}{\Omega} \sin(\Omega t) I) \]  

(14)

where \( H \) is the algorithm update period \( H = \text{time} - t_{n-1} \).

A typical coning motion is defined as [12]:

\[ \omega = [a \Omega \cos(\Omega t) J, d \Omega \sin(\Omega t) K] \]  

(15)

where \( a, d \) are the amplitudes of the angular oscillations in two orthogonal axes of the body. \( \Omega \) is the frequency associated with the angular oscillations. The corresponding true coning correction is [5, 8]:

\[ \beta = \frac{ad}{2} (\Omega H - \sin(\Omega t) I) \]  

(16)

Compared Eq. (14) with Eq. (16), we can find that Eq. (14) equals Eq. (16) when \( b \) in Eq. (14) are replaced by \( a \), and \( c \) in Eq. (14) are replaced by \( d \). This is because the coning motion equation Eq. (13) equals the sculling equation Eq. (15) when \( b \) in Eq. (13) is replaced by \( a \), and \( c \) in Eq. (13) is replaced by \( d \). Hence there is a duality between true coning correction and true sculling correction.
C. THE EQUIVALENCE BETWEEN THE OPTIMAL COEFFICIENTS OF CONING AND OF SCULLING ALGORITHMS

The sculling integral should equal the true sculling correction in a sculling environment.

\[ \Delta \hat{V}_{\text{scull}} = \Delta V_{\text{scull}} \]  

(17)

Also, the coning integral term given in Eq. (11) should equal the true coning correction in a coning environment. There is:

\[ \hat{\beta} = \beta \]  

(18)

As is stated, there are dualities between \( \Delta \hat{V}_{\text{scull}} \) and \( \hat{\beta} \), \( \Delta V_{\text{scull}} \) and \( \beta \). Hence the optimal coefficients of sculling algorithm using angular rate/specific-force input are equivalent to those of coning algorithm using angular rate input. The optimal coefficients of coning algorithms using angular rate input have been derived in Ref.4 [Eqs.(33), (36), and (42)]. So it is easy to obtain the corresponding sculling algorithm.

D. ALGORITHM EXAMPLES

This section converts two existing derived coning algorithms into their sculling algorithm counterparts.

1) EXAMPLE 1 2-INTERVAL OPTIMAL SCULLING ALGORITHM

In Eq.47 of Ref.4, the 2-interval optimal coning algorithm using angular rate input is:

\[ \hat{\beta} = \frac{h^2}{45} (\omega_x \times \omega_y) + \frac{28h^2}{45} (\omega_t \times \omega_t) \]  

(19)

where \( h \) is the sub-minor interval of the algorithm. For a 2-interval algorithm there is \( H=2h \). According to Eq.(19) and Eq.(A12) the 2-interval optimal sculling algorithm using angular rate/specific-force input can be obtained:

\[ \Delta \hat{V}_{\text{scull}} = \frac{H^2}{180} (\omega_t \times f_y + f_x \times \omega_t) + \frac{7H^2}{45} (\omega_t \times f_t + f_x \times \omega_t) \]  

(20)

2) EXAMPLE 2 3-INTERVAL OPTIMAL SCULLING ALGORITHM

In Eq.45 of Ref. 4, the 3-interval optimal coning algorithm using angular rate input is given as:

\[ \hat{\beta} = \frac{87h^2}{2240} (\omega_t \times \omega_t) + \frac{27h^2}{56} (\omega_t \times \omega_y) + \frac{2619h^2}{2240} (\omega_t \times \omega_t) \]  

(21)

where \( h \) is the subminor interval of the algorithm. For a 3-interval algorithm there is \( H=3h \). According to Eq.(21) and Eq.(A12) the 3-interval optimal sculling algorithm using angular rate/specific-force input can be obtained:

\[ \Delta \hat{V}_{\text{scull}} = \frac{29H^2}{6720} (\omega_t \times f_y + f_x \times \omega_t) + \frac{3H^2}{56} (\omega_t \times f_t + f_x \times \omega_t) \]  

+ \frac{29H^2}{2240} (\omega_t \times f_t + f_x \times \omega_t) \]  

(22)

E. DIGITAL INTEGRATION ALGORITHM FOR VELOCITY ROTATION

\( \Delta \theta_{\text{in}}, \Delta V_{\text{in}} \) in Eq.(5) can be calculated by digital integration. For example for a 2-interval system there is:

\[ \Delta \theta_{\text{in}} = \left( \frac{\omega_t}{6} + \frac{4\omega_t}{6} + \omega_t \right) H, \Delta V_{\text{in}} = \left( \frac{f_x}{6} + \frac{4f_x}{6} + f_x \right) H \]  

(23)

Substituting Eq.(23) into Eq.(5) gives the velocity rotation correction \( \Delta V_{\text{rot}} \) of 2-interval velocity rotation digital integration algorithm:

\[ \hat{V}_{\text{rot}} = \frac{1}{2} \left( \frac{\omega_t}{6} + \frac{4\omega_t}{6} + \omega_t \right) (f_x + \frac{4f_x}{6} + f_x) H^2 \]  

(24)

Then substituting Eqs.(23), (24) and (20) into Eq.(5), we obtain the integrated transformed specific-force increment \( \Delta V_{\text{sfm}} \) of a 2-interval system there:

\[ \Delta V_{\text{sfm}} = \Delta V_{\text{in}} + \Delta V_{\text{rot}} + \Delta V_{\text{scull}} \]  

\[ = \left( \frac{f_x}{6} + \frac{4f_x}{6} + f_x \right) H + \frac{1}{2} \left( \frac{\omega_t}{6} + \frac{4\omega_t}{6} + \omega_t \right) (f_x + \frac{4f_x}{6} + f_x) H^2 \]  

+ \frac{H}{180} (\omega_t \times f_y + f_x \times \omega_t) + \frac{7H^2}{45} (\omega_t \times f_t + f_x \times \omega_t) \]  

(25)

Described previously, \( \Delta V_{\text{g/\text{con}}/} \) in Eq. (2) can be calculated approximately as a constant. Considering \( V_{\text{in}} \) in Eq. (2), i.e., the carrier velocity at \( t_{n-1} \) has been calculated out during the last velocity determination iteration. By substituting Eq.(25) into Eq.(2) the carrier velocity at \( t_n \), i.e., \( V_{\text{n}} \) will be achieved.

IV. SCULLING ALGORITHM USING ANGULAR RATE/SPECIFIC-FORCE INCREMENTS INPUT

As is stated, some types of accelerometer have the output of specific-force increments now. If the IMU produce angular rate/specific-force increments outputs, the conventional sculling algorithms such as Eqs.(7) and (9) cannot calculate out the carrier’s velocity directly. The sculling velocity algorithm must include a step for converting angular rate into integrated angular rate by digital integration. This step will produce non-negligible computational error. To solve this problem, we have developed a novel sculling algorithm using angular rate/specific-force increments input directly.

A. FORMALIZED OPTIMAL SCULLING ALGORITHM

For an \( N \)-interval sculling velocity algorithm using angular rate/specific-force increments inputs, the sample number of the accelerometer outputs (specific force) is \( N+1 \), and the number of the gyro outputs (integrated angular rate) is \( N \).
The theoretical gyro/accelerometer outputs in a sculling environment defined by Eq.(15) are:

\[
\omega_i = \mathbf{b}_c \cos \{\Omega [l_{\omega} + (i-1)N] \} \Omega_j, \quad i = 1,2,\ldots,N+1
\]

\[
\Delta V_j = \frac{2c_2}{\sin 2N} \sin \Omega [l_{\omega} + (2j-1)N] \mathbf{K}, \quad j = 1,2,\ldots,N
\]

By the duality between coning correction and sculling correction, following the derivation of Eqs.(A8)-(A12) in Appendix, we can obtain:

\[
\Delta \dot{V}_{\text{scale}} = \Delta \dot{\Phi} \{[\omega + \Delta V] \rightarrow \omega\} - \Delta \dot{\Phi} \{\Delta V \rightarrow \omega\}
\]

where “A→B” represents the “B replaced by A”. For example, “” replaces by . Then substituting Eq.(27) into Eq.(11) gives the generalized form of the sculling correction using angular rate/specific-force increment input:

\[
\Delta \dot{V}_{\text{scale}} = \sum_{j=2}^{N} \sum_{i=1}^{N} K_{ij} (\omega_j \times \Delta V_j) \times (\omega_i \times \Delta V_i)
\]

\[
= \sum_{j=2}^{N} \sum_{i=1}^{N} K_{ij} (\omega_j \times \Delta V_j) H - \sum_{j=1}^{N} \sum_{i=1}^{N} K_{ij} (\Delta V_i \times \Delta V_j)
\]

\[
= \sum_{j=2}^{N} K_j (\omega_j \times \Delta V_j) H
\]

(28)

where \(N\) is the number of iteration intervals over the velocity update period. It follows from Eq.(26) that:

\[
(\omega_i \times \Delta V_j \rightarrow \omega) H
= bc \sin \frac{\Omega H}{2N} [\sin \frac{2j-2+1}{2N} \Omega H - \sin \frac{2j-2-1}{2N} \Omega H]
\]

\[
= bc \sin \frac{\Omega H}{N} \sin \left[\frac{j-i}{N} \Omega H\right]
\]

(29)

Obviously, the sculling correction \(\Delta V_{\text{scale}}\) is only determined by \([j-i]\). Therefore Eq.(28) can be simplified as:

\[
\Delta \dot{V}_{\text{scale}} = \sum_{j=2}^{N} k_{j-1} (\omega_j \times \Delta V_j - \omega_j \times \Delta V_j) H
\]

(30)

Substituting Eq.(26) into Eq.(30) gives:

\[
\Delta \dot{V}_{\text{scale}} = bc \Delta H \sum_{j=1}^{N-1} k_j \sin \frac{\Omega H}{N} \sin \frac{\Omega H}{N}
\]

(31)

Applying Eq.(31) with Taylor series expansion for the coefficient terms “\(\Omega H\)”, we obtain:

\[
\Delta \dot{V}_{\text{scale}} = bc \left[ k_1 + 2 k_2 + \ldots (N-1) k_{N-1} \right] (\Omega H)^2 + \left( \frac{k_1}{3} - \frac{k_2}{3!} \right) (\Omega H)^4 + \ldots
\]

(32)

Applying Eq.(14) with Taylor series expansion for the coefficient terms “\(\Omega H\)”, gives:

\[
\Delta V_{\text{scale}} = \frac{bc}{2} \left[ \frac{(\Omega H)^3}{3!}\Omega - \frac{(\Omega H)^5}{5!}\Omega + \ldots \right]
\]

(33)

From \(\Delta \dot{V}_{\text{scale}} = \Delta \dot{V}_{\text{scale}}\), we can obtain:

\[
A_{(N-1)\times(N-1)} \cdot G_{(N-1)\times1} = D_{(N-1)\times1}
\]

(34)

where:

\[
A = \begin{bmatrix}
1 & 1 & \ldots & 1 \\
2 & 2 & \ldots & 2 \\
\vdots & \vdots & \ddots & \vdots \\
N-1 & N-1 & \ldots & N-1
\end{bmatrix},
\]

\[
G = \begin{bmatrix}
k_1 \\
k_2 \\
\vdots \\
k_{N-1}
\end{bmatrix},
\]

\[
D = \begin{bmatrix}
1 \\
2 \\
\vdots \\
2(N-1)
\end{bmatrix}
\]

The solution to Eq.(34) is \(G = A^{-1}D\). Details regarding the optimal coefficients are shown in Table I.

**B. ALGORITHM EXAMPLES**

1) **EXAMPLE 1**  2-INTERVAL OPTIMAL SCULLING ALGORITHM

When \(N=2\), substituting \(k_1=1/3\) into Eq.(43) gives:

\[
\Delta \dot{V}_{\text{scale}} = \frac{1}{3} (\omega_1 \times \Delta V_2 - \omega_2 \times \Delta V_1) H
\]

(35)

The per unit time algorithm error is:

\[
\delta V_{\text{scale}} = \| \dot{V}_{\text{scale}} - V_{\text{scale}} \| = \frac{bc}{360} (\Omega H)^4
\]

(36)

In Eqs.(2) and (5), the integrated transformed specific-force increment \(\Delta V_{\text{scale}}\) is composed of \(\Delta V_{\text{scale}}\), \(\Delta V_{\text{scale}}\), and
ΔV_m, ΔV_n, and Δθ_m in Eq.(5) can be calculated by digital integration:

$$\Delta \hat{\theta}_m = (\frac{\alpha_1}{6} + \frac{4\alpha_2}{6} + \frac{\alpha_3}{6})H, \Delta \hat{V}_m = \Delta V_1 + \Delta V_2$$  \hspace{1cm} (37)

Substituting Eq.(37) into Eq.(5) gives:

$$\Delta \hat{V}_m = \frac{1}{2} (\frac{\alpha_1}{6} + \frac{4\alpha_2}{6} + \frac{\alpha_3}{6} + \frac{\alpha_4}{6}) \times (\Delta V_1 + \Delta V_2)H$$  \hspace{1cm} (38)

Substituting Eqs. (35), (37), and (38) into Eq.(5) gives the 2-interval integrated transformed specific-force increment:

$$\Delta \hat{V}_m = \Delta V_1 + \Delta V_2 + \frac{1}{2} \left( \frac{\alpha_1}{6} + \frac{4\alpha_2}{6} + \frac{\alpha_3}{6} \right) \times (\Delta V_1 + \Delta V_2)H$$  \hspace{1cm} (39)

$$+ \frac{1}{3} \left( \alpha_4 \times \Delta V_1 - \alpha_5 \times \Delta V_2 \right) H$$

2) EXAMPLE 2 3-INTERVAL OPTIMAL SCULLING ALGORITHM

When N=3, substituting k_1=23/40, k_2=7/80 of table I into Eq.(30) gives:

$$\Delta \hat{V}_m = \frac{23}{40} (\alpha_1 \times \Delta V_1 - \alpha_2 \times \Delta V_2) H + \frac{7}{80} \left( \alpha_1 \times \Delta V_1 - \alpha_5 \times \Delta V_2 \right) H$$  \hspace{1cm} (40)

For a 3-interval system there are:

$$\Delta \hat{\theta}_m = \frac{3\alpha_1}{8} + \frac{3\alpha_2}{8} + \frac{3\alpha_3}{8} + \frac{\alpha_4}{8} \times H, \Delta \hat{V}_m = \Delta V_1 + \Delta V_2 + \Delta V_3$$  \hspace{1cm} (41)

Substituting Eq.(41) into Eq.(5) gives the velocity rotation correction \( \Delta V_\text{rotm} \):

$$\Delta \hat{V}_\text{rotm} = \frac{1}{2} \left( \frac{3\alpha_1}{8} + \frac{3\alpha_2}{8} + \frac{3\alpha_3}{8} + \frac{\alpha_4}{8} \right) \times (\Delta V_1 + \Delta V_2 + \Delta V_3) H$$  \hspace{1cm} (42)

Then substituting Eqs.(40)-(42) into Eq.(5) gives the integrated transformed specific-force increment \( \Delta V_\text{sfm} \):

$$\Delta \hat{V}_\text{sfm} = \epsilon_0 + \Delta \hat{V}_\text{rotm} + \Delta \hat{V}_\text{sculm}$$

$$= \Delta V_1 + \Delta V_2 + \Delta V_3 + \frac{1}{2} \left( \frac{3\alpha_1}{8} + \frac{3\alpha_2}{8} + \frac{3\alpha_3}{8} + \frac{\alpha_4}{8} \right) \times (\Delta V_1 + \Delta V_2 + \Delta V_3) H$$  \hspace{1cm} (43)

$$+ \Delta V_3 H + \frac{23}{40} \left( \alpha_1 \times \Delta V_1 - \alpha_2 \times \Delta V_2 \right) H + \frac{7}{80} \left( \alpha_1 \times \Delta V_1 - \alpha_5 \times \Delta V_2 \right) H$$

Described previously \( \Delta V_\text{gcon} \) in Eq. (2) can be calculated out easily, indeed it can be calculated approximatively as a constant during one update period and omitted here. \( V_{\text{con}} \) in Eq.(2), i.e., the carrier velocity at \( t_{m-1} \) has been calculated out during the last algorithm update period. Thus the carrier velocity at \( t_m \) can be calculated out by substituting Eq.(43) into Eq.(2).

Comparing the proposed sculling algorithm given by Eq.(35) and (40) with the conventional sculling algorithms represented in Eqs.(7) and (9), we can see the advantages of the proposed algorithm are that it is able to calculate out the sculling correction, then the velocity at \( t_m \) directly without any demands for the dimension conversion of inertial sensor outputs.

V. SIMULATIONS

According to the sculling motion given by Eq.(13), we employ a 600-second digital simulation to verify the performance of the proposed sculling algorithm using angular rate/specific-force increments input. The parameters are set as: the amplitude of the angular vibration \( b=1^\circ \), the amplitude of the specific-force vibration \( c=10g \), the frequency associated with the angular and specific-force oscillations \( \Omega=2\pi \text{ rad/s} \) (oscillation frequency is 1 Hz). The inertial sensors outputs are given by Eq.(26) with \( N=3 \). The velocity update period \( H=0.01\text{s} \).

The initial velocity is \( (0, 0, 0) \text{ m/s} \). The initial position is \( (118.78333^\circ, 32.05000^\circ, 0.01\text{s}) \). The navigation coordinate frame is set to east-north-up. The error comparisons between the proposed 3-interval sculling algorithm given by Eq.(40) and the conventional 3-interval sculling algorithm given by Eq.(7) are shown in Figs. 1–2. The blue and solid curve is the curve of proposed sculling algorithm errors, the red and dotted curve is the curve of conventional sculling algorithm errors.

From Fig. 1 we can see that the eastward velocity errors of both algorithms are larger about one order than northern velocity errors. This is because in a sculling environment defined by Eq.(13), the sculling error mainly exists in the x-axis of the carrier. The corresponding velocity component is \( \dot{V}_E \) in the east-north-up coordinate frame. So there is a constant error term in the eastward velocity, which is called “sculling error”.

So both eastward velocity error curves increase almost linearly with time due to the sculling error propagation.

However, both the \( \dot{V}_E \) error and the \( V_N \) error of the proposed algorithm is approximately reduced by 10 times compared with those of the traditional algorithm. This is because the proposed sculling algorithm can calculate out the velocity directly without dimension conversion of
inertial sensor outputs. Therefore, the sculling correction has been compensated more effectively and the velocity determination precision is improved dramatically.

To further illustrate the accuracy of the proposed algorithm, we make a quantitative comparison. The results of comparison are given in table II:

<table>
<thead>
<tr>
<th>Errors</th>
<th>Algorithms</th>
<th>Eastward velocity error ($V_E$)</th>
<th>Northward velocity error ($V_N$)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Mean (m/s)</td>
<td>Variance ($m^2/s^2$)</td>
<td>Mean (m/s)</td>
</tr>
<tr>
<td>The developed algorithm</td>
<td>8.78e-004</td>
<td>3.18e-007</td>
<td>-4.46e-005</td>
</tr>
<tr>
<td>The traditional algorithm</td>
<td>8.08e-003</td>
<td>2.69e-005</td>
<td>4.11e-004</td>
</tr>
</tbody>
</table>

For straight comparison, we draw a bar graph named Fig.2, based on the data of table II:

![Comparison of the statistical characters of the velocity error between two algorithms.](image)

We also compared the attitude errors of two algorithms. The results are given in Fig.3:

<table>
<thead>
<tr>
<th>Errors</th>
<th>Algorithms</th>
<th>Roll error($\delta\gamma$)</th>
<th>Pitch error($\delta\theta$)</th>
<th>Head error($\delta\psi$)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Mean (°)</td>
<td>Variance (°)$^2$</td>
<td>Mean (°)</td>
<td>Variance (°)$^2$</td>
</tr>
<tr>
<td>The developed algorithm</td>
<td>-1.85 e-006</td>
<td>8.47 e-012</td>
<td>-1.33 e-009</td>
<td>5.04 e-018</td>
</tr>
<tr>
<td>The traditional algorithm</td>
<td>1.70 e-005</td>
<td>3.07 e-010</td>
<td>1.23 e-008</td>
<td>4.27 e-016</td>
</tr>
</tbody>
</table>

As is seen in Fig.3, the attitude errors of the developed algorithm are much less than those of the traditional algorithm. This is because the improved precision in velocity determination can also result in the improvement of the precision of attitude determination.

To further illustrate the accuracy of the developed algorithm, we make a quantitative comparison. The results of comparison are given in table III and Fig. 4:

<table>
<thead>
<tr>
<th>Errors</th>
<th>Algorithms</th>
<th>Roll error($\delta\gamma$)</th>
<th>Pitch error($\delta\theta$)</th>
<th>Head error($\delta\psi$)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Mean (°)</td>
<td>Variance (°)$^2$</td>
<td>Mean (°)</td>
<td>Variance (°)$^2$</td>
</tr>
<tr>
<td>The developed algorithm</td>
<td>-1.85 e-006</td>
<td>8.47 e-012</td>
<td>-1.33 e-009</td>
<td>5.04 e-018</td>
</tr>
<tr>
<td>The traditional algorithm</td>
<td>1.70 e-005</td>
<td>3.07 e-010</td>
<td>1.23 e-008</td>
<td>4.27 e-016</td>
</tr>
</tbody>
</table>

In Fig.4 the bar of pitch error $\delta\theta$ is invisible because the pitch errors of both algorithms are so small (seen in table III) that actually they can be neglected compared with the roll error and head error.

We also compare the position error of two algorithms. The results are given in Fig. 5:
Similarly, let the traditional sculling algorithm. This is because the eastward velocity error is the key cause for the longitude error. As mentioned above, the eastward velocity errors of both algorithms are larger than the latitude errors. However, the position errors of the proposed algorithm are reduced by about one order of magnitude compared with those of the traditional sculling algorithm. This is because the improved precision in velocity determination will also improve the precision of position determination.

**VI. CONCLUSIONS**

To solve the issue that in certain situations the dimensions of the IMU output do not meet the demand of the conventional sculling algorithms for input, the optimal sculling algorithms using angular rate/specific-force and angular rate/specific-force increments inputs are developed in this paper. The developed sculling algorithms can directly calculate out the velocity of the carrier without the dimension conversion of inertial sensor outputs. Accordingly, the developed algorithms provide higher precision than conventional sculling algorithms in the SINS in which the employed gyro has an angular rate output. Our novel sculling velocity algorithm thus has great useful value in such cases.

**APPENDIX: THE DERIVATION OF DUALITY EQUIVALENCY BETWEEN CONING INTEGRAL AND SCULLING INTEGRAL**

Let us define a vector $U_1$ to be the integral of the cross product of two vectors $V_1$ and $v_1$:

$$U_1 = \int (V_1 \times v_1) dt$$  \hspace{1cm} (A1)

where $V_1 = \int v_1 dt$. Similarly, let $U_2$ be the integral of $V_2 \times v_2$, where $v_2$ is another arbitrary vector:

$$U_2 = \int (V_2 \times v_2) dt$$  \hspace{1cm} (A2)

where $V_2 = \int v_2 dt$. Because $U_1$ and $U_2$ have identical mathematical forms, $U_2$ equals $U_1$ when $v_1$ in $U_1$ is replaced by $v_2$.

Now define the following:

$$V_3 = v_1 + v_2 \hspace{1cm} U_3 = \int (V_3 \times v_3) dt$$  \hspace{1cm} (A3)

where:

$$V_3 = \int v_3 dt = \int (v_1 + v_2) dt = V_1 + V_2,$$

$$U_3 = \int (V_3 \times v_3) dt = U_1 + U_2 + \int (V_1 \times v_2) dt + \int (V_2 \times v_1) dt$$  \hspace{1cm} (A4)

Let:

$$U_4 = \int [(V_1 \times v_2) + (V_2 \times v_1)] dt$$  \hspace{1cm} (A5)

Comparing Eq.(A5) with Eqs.(A1)-(A3) gives:

$$U_4 = U_3 - U_1 - U_2$$  \hspace{1cm} (A6)

Then $U_4$ can be represented as:

$$U_4 = U_1(v_1 \rightarrow v_3) - U_1(v_2 \rightarrow v_1)$$  \hspace{1cm} (A7)

where “A→B” represents the “B replaced by A”. For example, “$v_1 \rightarrow v_3$” means that $v_1$ is replaced by $v_3$.

**FIGURE 5. Comparison of the horizontal position determination results between two algorithms under sculling environment.**

**FIGURE 6. Comparison of the statistical characters of the position error between two algorithms.**
Let us also define $\hat{U}_1$ to be a digital integration algorithm for $U_1$. Similarly, $\hat{U}_2$ for $U_2$, $\hat{U}_3$ for $U_3$, and $\hat{U}_4$ for $U_4$. It can be followed from Eqs. (A6)-(A7) that:

$$\hat{U}_4 = \hat{U}_3 - \hat{U}_1 - \hat{U}_2 = \hat{U}_3(v_1 \to v_1) - \hat{U}_1(v_2 \to v_1)$$  \hspace{1cm} (A8)

Let:

$$V_1 = \omega, v_2 = f, v_3 = \omega + f, V_4 = \int v_1 dt = \Delta \theta(t),$$

$$V_2 = \int v_2 dt = \Delta V(t), V_3 = \Delta \theta(t) + \Delta V(t)$$  \hspace{1cm} (A9)

Then we can get:

$$\Delta \Phi = \frac{1}{2} \int \Delta V(t) \times \omega dt = \frac{1}{2} \hat{U}_1$$

$$\Delta \dot{\Phi}_\text{sculm} = \frac{1}{2} \left[ \Delta \theta(t) \times f + \Delta V(t) \times \omega \right] dt = \frac{1}{2} \hat{U}_4$$  \hspace{1cm} (A10)

Substituting Eq.(A8) into $\Delta \dot{\Phi}_\text{sculm}$ of Eq.(A10) can obtain the coning integral value:

$$\Delta \dot{\Phi}_\text{sculm} = \frac{1}{2} \hat{U}_4 = \frac{1}{2} \left[ \hat{U}_1(v_1 \to v_1) - \hat{U}_1(v_2 \to v_1) \right]$$  \hspace{1cm} (A11)

Substituting Eqs.(A9)-(A10) into Eq.(A11) gives:

$$\Delta \dot{\Phi}_\text{sculm} = \Delta \Phi(\omega + f) \to \omega) - \Delta \Phi - \Delta \Phi(f \to \omega)$$  \hspace{1cm} (A12)

ACKNOWLEDGMENT

The authors would like to acknowledge postgraduate student Di Sang for his work in the digital simulations. We also gratefully acknowledge the helpful comments and suggestions of English editors and reviewers.
